In 2005, the BJS released its first study of sexual violence identified through a national review of administrative records in adult correctional facilities (Survey of Sexual Victimization), determining that there were 8,210 allegations of sexual violence reported nationwide during 2004. Using this same methodology over time, BJS reports that allegations continue to increase (primarily due to increases in allegations by those in jails), although substantiation rates do not, hovering around 10%.

In 2011–2012, using the National Inmate Survey, it was estimated that 4.0% of state and federal prison inmates and 3.2% of jail inmates reported experiencing one or more incidents of sexual victimization by another inmate or facility staff in the previous 12 months (or since admission to the facility if incarcerated fewer than 12 months). The percentage has not changed significantly across three data collection periods: 4.5% in 2007, 4.4% in 2008–2009, and 4.0% in 2011–2012 among prison inmates; and 3.2% in 2007, 3.1% in 2008–2009, and 3.2% in 2011–2012 among jail inmates. Female inmates, however, had victimization rates 4 times higher than that of male inmates, and inmates with a mental illness were at substantially higher likelihood of being sexually assaulted by a fellow inmate. Among inmates who have been released, the National Former Prisoner Survey

found that 10% reported being sexually victimized while incarcerated.

Sexual victimization appears to be perpetrated about equally by inmates (51%) and by staff (40%), although the profile of inmate-on-inmate sexual victimization differs from that of staff-on-inmate victimization. In 2011, both victims and perpetrators of inmate-on-inmate nonconsensual sexual acts were predominately (90%) male. Sexual victimization most frequently (50%) occurred in the victim's cell or room. Nearly half (44%) of these incidents involved physical force, with an injury occurring in 18% of the incidents. The most frequent consequence for inmate-on-inmate offenses is solitary confinement (73%). However, offenders were subjected to legal action in half (48%) of substantiated nonconsensual acts and 19% of incidents involving abusive sexual contact.

In 2011, staff-on-inmate sexual victimization most frequently occurred in a service area (48%). Only 11% of incidents involved physical force, with an injury occurring in less than 1% of the incidents. More than half (54%) of the substantiated sexual misconduct and a quarter (26%) of the sexual harassment incidents were committed by female staff. Although any physical relationship between staff and inmates is illegal in all 50 states, female staff-on-inmate incidents overwhelmingly (84%) appeared to be willing compared to 37% of those perpetrated by male staff. The majority (78%) of offenders, regardless of gender, were fired or resigned, with 45% being arrested, referred for prosecution, or convicted.

Recommendations for Reducing Prison Rape

Emanating from PREA, the NPREC was convened in June 2004 to develop recommendations for reducing prison rape that would be conveyed to Congress in the form of a report. In 2009, the NPREC submitted 41 recommendations to Congress. However, it was not until 2012 that the "National Standards to Prevent, Detect, and Respond to Prison Rape Under the Prison Rape Elimination Act (PREA)," or PREA standards as they are known, were adopted and published in the Federal Register.

The 50 recommendations are divided into 13 categories: Prevention Planning (eight recommendations), Responsive Planning (two recommendations), Training and Education (five recommendations), Screening for Risk of Sexual Victimization and Abusiveness (three recommendations), Reporting (four recommendations), Official Response Following Inmate Report (eight recommendations), Investigations (three recommendations), Discipline (three recommendations), Medical and Mental Care (three recommendations), Data Collection and Review (four recommendations), Audits (one recommendation), Auditing and Corrective Action (five recommendations), and State Compliance (one recommendation).

Upon the adoption of these standards, states had 2 years to develop and implement policies and programs to meet these standards. As of the May 15, 2014, deadline, eight states were subject to penalty for being out of compliance, subjecting the state to a 5% reduction in certain U.S. Department of Justice grant funding. However, only two states were in full compliance. The remaining 46 states and territories submitted assurances, meaning that most states remain in the development stage of their response to PREA.

Risk Assessment of and for Prison Rape and Violence

As part of the final rules published by the Department of Justice in 2012, all inmates had to be assessed during the intake process and at the time of transfer concerning their risk of being sexually abused or sexually abusive toward other inmates. This screening was to occur within 72 hr of their placement using an objective screening instrument, with the information obtained being used to inform decisions about the inmate's housing, cell assignment, security level, work and educational assignments, and programming needs and interventions. In 2012, it was widely accepted that there was no nationally validated, PREA-specific risk assessment tool available, and it was understood that this type of validation would be cost prohibitive for most small agencies. The federal rules therefore focused exclusively on the identification of certain objective risk factors that were believed to be associated with sexual abuse and abusiveness in prison and which could be used by all staff with adequate training to

assess each inmate's risk of victimization and abuse in a timely manner.

For sexual victimization, the risk factors that were identified included whether the inmate had a mental, physical, or developmental disability; whether the inmate was under the age of 21 years; whether the inmate was of small stature; whether the inmate was being incarcerated for the first time; whether the inmate's history was exclusively non-violent; whether the inmate had prior convictions for sexual offenses against children or adults; whether the inmate was perceived to be gay, lesbian, bisexual, transgendered, intersex, or gender nonconforming; whether the inmate had previously experienced sexual victimization; the inmate's own perceptions of vulnerability; and whether the inmate was being detained solely for civil immigration purposes. For sexual abusiveness, the screening risk factors included whether the inmate had a prior institutional history of violence or sexual abuse perpetration, prior sexual abuse perpetration in the community, and prior convictions for violent offenses. The standards further required that the decision to assign a transgender or intersex inmate to a facility for male or female inmates be based on a case-on-case assessment of the inmate's health and safety and the impact of each type of placement on management and facility security.

Not long after the initial sponsoring of the PREA legislation, the National Institute of Justice also issued a solicitation for research concerning the assessment of risk of sexual victimization and sexual violence in prisons and jails. This research examined a broad array of validated risk factors associated with other forms of violence in the community and in prison. These included the effects of early childhood adverse experiences and adolescent violence, prior community and institutional violence and victimization, patterns of sexual adaption prior to incarceration, affective and perceptual states experienced by men and women while incarcerated, personality traits and disorders including psychopathy, and the use of structured violence risk instruments developed for assessing the risk of violence in community and inpatient treatment settings. This research found that there were pronounced gender differences in the risk factors that were associated with sexual violence and victimization in prison and that the experience of violence and victimization often

co-occurred, particularly in the experiences of incarcerated men. The research also found that a wide array of risk factors was associated with different types of sexual experiences in prison, including prior historical experiences and events, personality factors and emotional states, relationships and behavior since being incarcerated, and attributes of the correctional system itself as reflected in state differences in rates of both sexual victimization and violence.

Programming and Audits

Programming

Programmatically, PREA sought to create a zero-tolerance standard for the incidence of prison rape, to make prison rape prevention a top priority in each prison system, and to create national standards for the detection, prevention, reduction, and punishment of prison rape. The PREA standards are reflected in the programs being implemented at institutions. For most institutions, programs and protocols had to be developed for inmate orientation, reporting and investigation, and responding to victims, among many others. Each state is required to have a PREA coordinator to assist in developing and implementing the PREA standards.

Perhaps the easiest standard to implement was the development of awareness materials that could be distributed to inmates during orientation (e.g., videos or pamphlets on how to protect oneself from prison sexual assault). More challenging was the development of protocols for inmate reporting of sexual assault and correctional staff investigations of those allegations as well as the development of procedures for responding to victims of sexual assault. Some correctional facilities are collaborating with sexual assault victim service providers in the community to provide these services since they have the expertise to respond to these cases.

Audits

To ensure compliance with the PREA standards, audits were implemented. All confinement facilities covered under PREA standards are audited at least every 3 years, with one third of each facility type operated by an agency, or private organization on behalf of an agency, audited each year. Audits are conducted using an

instrument developed by the PREA Resource Center in conjunction with the U.S. Department of Justice that reflects the PREA standards. Audits are thorough and typically take up to 5 days to complete. If the PREA auditor determines that the facility *does not meet standard* with respect to any standard provision, the auditor and the agency will jointly develop a corrective action plan.

Taken as a whole, PREA suggested a clear-cut commitment to reducing sexual violence in prisons and jails and provided financial incentives for research and robot programming. However, to date, many state systems are still developing materials and protocols to meet the requirements. Whether such activity results in greater safety for inmates remains an empirical question.

SEXUAL VIOLENCE RISK-20 (SVR-20)

Risk assessment of sexual offenders is an important topic in forensic psychiatry and psychology. Practitioners are given the responsibility of completing risk assessments of offenders to try to maximize public safety and encourage responsible management, both of which depend on effective intervention and supervision. The basis of the development of the SVR-20 was to utilize structured professional judgment (SPJ) to inform risk management to, in turn, maximize public safety, the latter being viewed as the ultimate objective of all risk assessment work. This entry focuses on the SVR-20 and its revised version, discussing its guidelines.

SVR-20 Guidelines

The SPJ approach to risk assessment exemplified by the SVR-20 is based on the use of structured clinical guidelines to help the assessor formulate a risk depiction of the individual being assessed. The use of such guidelines assumes that (a) the assessment is being done by a professional who has been trained, (b) the guidelines include the most important risk factors that should be minimally considered by the evaluator, and (c) the evaluator must use discretion as to how information regarding risk factors is to be combined through the SPJ approach to reach final judgments regarding risk.

The SVR-20 guidelines for assessing risk of sexual violence have been widely adopted by clinicians around the world because of the flexibility of the method. The instrument allows for the analysis of various aspects of risk including not just likelihood of reoffense, but also nature, imminence, victim specificity, and severity (e.g., lethality). The SVR-20 guidelines also allow assessors to consider a range of factors that are relevant to the risk assessment at hand, including issues related to

sexual disorders (paraphilias) that may be reflected in criminal behavior, such as sadism, fetishism, or pedophilia, all of which help to inform the risk management of the individual being assessed.

The original SVR-20, published in 1997, comprised 20 risk factors in three domains: Psychosocial Adjustment, Sexual Offenses, and Future Plans. The domain of Psychosocial Adjustment included sexual deviation, victim of child abuse, psychopathy, major mental illness, substance use problems, suicidal/homicidal ideation, relationship problems, employment problems, past nonsexual violent offenses, past nonviolent offenses, and past supervision failures. Sexual Offenses included high-density sex offenses, multiple sex offense types, physical harm to victims in sex offenses, use of weapons or threats of death in sex offenses, escalation in frequency or severity of sex offenses, extreme minimization or denial of sex offenses, and attitudes that support or condone sex offenses. Future Plans included lacks realistic plans and negative attitude toward intervention. The inclusion of each item was supported by the systematic review of the scientific and professional literatures.

Since its publication, and despite some criticisms, the SVR-20 has been evaluated by a variety of researchers in a variety of sites internationally and is considered the best validated SPJ for the risk assessment of sexual offenders. There are a large number of studies showing good to excellent levels of interrater reliability. According to several empirical studies and meta-analyses, judgments of risk made using the SVR-20 have predictive validity that is comparable to other risk assessment instruments.

Revised Version

In 2017, the SVR-20 was updated in a second version to reflect developments in the research literature and changes in treatment foci over the past decade. Although the content of the second version of SVR-20 is similar to that of the original guidelines in broad terms, a number of specific changes were made: The definitions of some risk factors were clarified; the three specific risk factors related to general criminality (i.e., past nonsexual violent offenses, past non-violent offenses, and past supervision failures) were collapsed to

create a more general risk factor *nonsexual criminality*; and two new risk factors (reflecting problems related to sexuality and sexual offenses) were added to the instrument (*sexual health problems* and *psychological coercion in sexual offending*).

In the second version of the SVR-20, the domain of Psychosocial Adjustment includes sexual deviation, sexual health problems, victim of child abuse, psychopathic personality disorder, major mental illness, substance abuse problems, suicidal/homicidal ideation, relationship problems, employment problems, and nonsexual offending. Sexual Offenses include chronic sexual offending, diverse sexual offending, physical harm in sexual offending, psychological coercion in sexual offending, escalation in sexual offending, extreme minimization or denial of sexual offenses, and attitudes that support or condone sexual offences. Future Plans include lacks realistic plans, negative attitudes toward intervention, and negative attitude toward supervision. The revisions ensure that the SVR-20 is comprehensive in scope, sensitive to both dynamic and static aspects of risk, and useful in the development of risk management plans.

Criticisms

It is likely that the second version of the SVR-20 will be subject to the same criticisms as the original manual. First, some critics will object to the inclusion of risk factors in the guidelines that are not established in the scientific literature as significant predictors of sexual reoffense. Because the revised SVR-20—like the original—uses a broad definition of sexual violence risk, the risk factors may be predictive of the nature, severity, or imminence of reoffense, rather than the likelihood, or the factors may be related to risk management rather than the likelihood of reoffense.

Second, some will object to the fact that the guidelines will be published *without validation research*. This criticism reflects a fundamental misunderstanding of the SPJ approach. It is true that the content of both the original and the second version of the SVR-20 was not based on a single piece of empirical research; instead, they were based on a systematic review of scores—even

hundreds—of empirical studies as well as a review of the professional literature.

Third, some will object to the fact that the revised SVR-20 will not yield a quantitative estimate of the probability of reoffense. This is correct; the goal of both versions of the SVR-20 is to guide risk management decisions and prevent reoffense, not to predict what might happen if the offender were provided treatment or simply monitored—most of the Actuarial risk assessment instruments (ARAI) do not differentiate risk across such clearly different scenarios, hence limiting their usefulness for risk management. The second version also provides the user with example worksheets for gathering information, coding the presence of risk factors (past and recent presence), and formulating conclusory opinions.

Research

In 2007, Karl Hanson and Kelly Morton-Bourgon Robert suggested that “for those wishing to understand their cases, there are a number of risk assessment tools available, although the research on these instruments is much less developed than the research on empirical actuarial measures (i.e., ARAIs)” (p. 16), and these authors go on to suggest the SVR-20 as one such measure (that presumably would help assessors understand their cases). However, it is clear that practitioners who conduct risk assessments do wish to understand the uniqueness of their cases. The SVR-20 instruments provide a framework for that understanding.

The SVR-20 was promoted initially as an aide-mémoire or report-writing assessment and guide. Early findings showed that the risk levels reached by SPJ based on supervision and treatment needs were found to have good predictive validity. A large amount of independent research has shown that well-guided professional judgment permits clinicians to make allowances for the uniqueness of their clients and that such judgments have better predictive validity than actuarial tests on average. Logically, this makes some sense: The individual is never accurately represented by the group average; and the corollary is also true, a group of individual predictions (e.g., via the SVR-20) ought to outperform a group average (when the SVR-20 is used actuarially it does not predict as well as when it is used in a SPJ manner). Regardless of the state of

the risk assessment literature, courts and parole boards around the world demand risk assessments from psychologists and psychiatrists on which to base their decisions. It is the responsibility of these psychologists and psychiatrists to provide their best risk formulation on the patient while acknowledging the limitations of the field. Furthermore, it is also their responsibility to advise policy and law makers regarding effective risk methodologies and to encourage research in this regard. To that end, the SVR-20 not only provides a basis for decisions that affect an offender's life but also decisions that could affect the life of potential victims.

SEXUALLY VIOLENT PREDATOR LAWS

This entry addresses a group of laws, originating in the early 1990s, known as *sexually violent predator* (SVP) laws. These laws use *civil* confinement (in contrast to criminal incarceration) to lock up individuals who are viewed as at high risk of committing a sexual offense in the future. Because these laws deprive people of their liberty in anticipation of a predicted crime, they are highly controversial legally as well as morally. This entry describes these laws as well as their legal context, traces their history, discusses the justifications as well as critiques, and concludes with a discussion of their current status.

Definition and Context of SVP Laws

SVP laws are civil commitment laws designed to identify individuals who pose a high risk of future sexually harmful behavior and commit them to indeterminate confinement in secure *treatment centers*. The stated purpose of the laws is to protect society from sexual violence by incapacitating those at highest risk of recidivist sexual violence. To comply with constitutional norms (discussed later in this entry), these programs are aimed only at individuals whose future risk is associated with some form of mental disorder or *abnormality*. Treatment for the sexual dangerousness must be provided.

SVP laws are one aspect of a suite of legal innovations that developed in the 1990s, all of which are aimed at the prevention of future sexual recidivistic offending by means outside of the criminal justice system. Other laws require sex offenders to register with law enforcement, classify sex offenders by risk, provide for the notification of the public about sex offenders who are being released to the community, and (in a growing number of jurisdictions) place geographic restrictions on where sex offenders may live or visit.

Many of these prevention laws impose long-term or lifelong burdens and obligations on sex offenders, but the SVP laws are the most drastic in that they involve long-term total confinement. For this reason, SVP laws are the most narrowly aimed and require the most comprehensive judicial due process. Although there is substantial variation among the state and federal SVP laws, they share key characteristics. SVP laws impose three criteria for commitment: (1) a history of sexually harmful behavior, (2) a mental disorder or abnormality, and (3) resulting in an elevated risk of future harmful sexual behavior. The laws are generally aimed at convicted sex offenders who are scheduled for release from prison, and all establish a system for screening incarcerated sex offenders who are nearing the completion of their prison sentences. Those who may meet the criteria of commitment are referred to as *prosecutors*, who then make the determination whether to petition a court for commitment.

Upon the filing of such a petition, the offender (referred to as the *respondent*) is generally assigned a defense lawyer, and expert examiners are appointed (in some instances also selected by the respondent) to evaluate the mental status and risk of the individual. A trial is held, and a decision about commitment is rendered, in some states by a jury, and in others by a judge. Some laws use the criminal law standard *beyond a reasonable doubt*, but others use the lower *clear and convincing evidence* standard. Upon a finding that the individual satisfies the legal criteria, the individual is committed, most often to a highly secure treatment facility, but in some instances to a *less restrictive* community setting subject to extensive supervision and control.

Some SVP laws provide for periodic reassessment of risk and mental condition, and all provide for some form of release if the individual's risk is diminished. All of the laws specify that some form of treatment is to be provided. There is great variability in the actual implementation of these legal provisions.

The Distinction Between Civil and Criminal Laws

All SVP laws claim to be *civil regulation* of liberty, in contrast to criminal punishment. The distinction is an important one and critical to an understanding of the legal context for SVP laws. The criminal justice system is the primary tool that the

government has to address antisocial violence, which permits the government to impose the most burdensome consequences on individuals, including depriving them of their liberty through imprisonment and, in the most extreme cases, imposing the death penalty. But the U.S. Constitution imposes numerous constraints on criminal punishment, as a bulwark against the kind of *tyranny* that led to the American Revolution: It can be imposed only after an individual is charged with a specific crime, at a specified time and place, in violation of specific, previously enacted laws, by a jury's verdict *beyond a reasonable doubt*. The government is forbidden to make something a crime retroactively (ex post facto laws) and cannot try a person for the same crime twice or increase a sentence after it is imposed (prohibition on double jeopardy). A person cannot be punished for a *status* (e.g., addiction or dangerousness), and no one may be forced to testify in a self-incriminating manner.

But these limits apply only to criminal procedures. The U.S. legal system permits certain forms of civil liberty-deprivation that fall outside of those protections. Traditional forms include involuntary treatment for severe mental illness, enforced quarantine and isolation for contagious diseases, and, now, discredited interventions like forced sterilization of mentally impaired individuals and the internment of U.S. citizens of Japanese descent during the World War II. The constitutional question is whether the government may properly classify SVP laws as *civil* and thus avoid the protections of the criminal law. The U.S. Supreme Court has ruled that SVP laws, at least on their face, are legitimate civil laws. The rulings are discussed in the next section.

History

First-Generation Laws

Beginning in the late 1930s, about half of the states adopted the so-called sex psychopath laws. Arising from the progressive movement and the emerging influence of psychiatry, these laws posited that certain sex offenders were more sick than bad and thus should be diverted from the criminal justice system to psychiatric institutions where they could be treated. Paralleling traditional civil commitment laws, the new laws sought to expand the concept of *insanity* to include the idea of

moral insanity, the rough equivalent of the present-day concept of antisocial personality disorder. But these laws, as drafted, were exceedingly vague and broad, and in a rare move (for that era), the Supreme Court, in *Minnesota ex Rel. Pearson v. Probate Court* (1940), insisted on narrowing their application to individuals who had an *utter lack of power to control* their dangerous sexual impulses.

In the early years, sex psychopath laws were aimed at offenders who were viewed as *too sick* for punishment, diverting them from the criminal justice system. Most of those diverted were non-violent offenders, many of whom were gay men whose offenses were engaging in consensual sex with other men. But child molesters were also included, though the underlying reason for diverting these individuals was that child molestation did not have the same severe character as forcible rape.

By the late 1970s and early 1980s, these laws fell into disuse following several authoritative studies that questioned fundamental assumptions underlying these laws, demonstrating that committed offenders were not distinguished by any psychiatric condition that was treatable and that dangerousness could not be identified in a reliable manner.

Second-Generation Laws

Context for Enactment

A decade or so after the demise of the first generation, a second generation of sex offender commitment laws arose. The new SVP laws espoused a markedly different aim: to identify, and confine, sex offenders too dangerous to release from prison. Eventually, 20 states and the federal government would enact SVP laws. The first SVP laws, in Washington state and Minnesota, were reactions to heinous sex crimes committed by recently released sex offenders. Several factors converged to shape this particular reaction to sexual violence. Feminists argued that sexual violence required more forceful and widespread responses, and conservatives pushed a law-and-order agenda. Because of constitutional limitations, broadened definitions of sexual assault and increased sentences could not be applied retroactively and thus did not immediately address the

problem of the release of dangerous offenders from prison, so policy makers turned to civil commitment as a solution.

Although feminists and conservatives shared the goal of harsher punishment for sex offenders, much of the feminist agenda was troubling for social conservatives. Feminists argued that violence against women was a widespread phenomenon, allowed to flourish because of the widely accepted myths and attitudes they said characterized patriarchy. Conservatives took the position that true sexual violence was aberrational and abnormal, the result of individual depravity rather than flawed societal norms. The SVP laws, based on the mental disorder model of sexual dangerousness, provided a vehicle for conservatives to address the feminist call to take sexual violence seriously, while adopting the aberrational view of sexual violence that conservatives espoused.

Initial Legal Challenges

The newly adopted SVP laws were immediately challenged on constitutional grounds. In 1997, the Supreme Court, in a split decision, upheld the constitutionality of these laws, based largely on a *facial* analysis of the language of the laws (*Kansas v. Hendricks*). The Court addressed and rejected two related challenges. The first asserted that the SVP laws were a form of criminal punishment and that they therefore violated key constitutional limitations on criminal law: the prohibitions on ex post facto laws and double jeopardy. The other challenge was based on the concept of *substantive due process*, a constitutional principle that places limits on the circumstances justifying the state's deprivation of an individual's liberty. The two arguments are related to each other. The states argued that the SVP laws were not punishment because they were civil commitment laws, long recognized as constitutionally legitimate. Challengers argued that SVP laws were not bona fide commitment laws, and therefore violated substantive due process, and could not be classified as civil rather than penal.

The challenges turned on whether SVP laws were bona fide civil commitment laws. Relying on a prior Supreme Court case (*Foucha v. Louisiana*), the challengers argued that the SVP laws do not fall within this traditional category because they

do not require proof of a valid mental illness. Challengers argued that terms defining the commitment class were not either *medically valid* (e.g., *mental abnormality*) or, though medically valid, *mental illnesses* (e.g., *personality disorder*). The Court rejected these arguments. While acknowledging that commitment requires some *mental disorder* predicate, the Court held there was no particular constitutional significance to the term *mental illness*; thus, *mental abnormalities* were not categorically ineligible to be constitutional predicates for commitment. In a later case, *Kansas v. Crane*, the Court held that "there must be proof of serious difficulty in controlling behavior . . . [that] must be sufficient to distinguish the dangerous sexual offender whose serious mental illness, abnormality, or disorder subjects him to civil commitment from the dangerous but typical recidivist convicted in an ordinary criminal case."

The Court also noted that the SVP laws adhered to the key indicia of civil commitment laws. In particular, they required that available treatment be provided and that an individual must be released from commitment just as soon as the circumstances justifying commitment no longer obtain. Challengers argued that the state had failed to provide effective treatment to committed individuals, supporting their argument that incarceration, rather than treatment, was the primary goal of the legislation. But the Court rejected this argument because the newness of the laws excused the rather *meager* treatment programs and held that treatment could be a purpose secondary to the primary purpose of incapacitation.

Growth of the Programs

Subsequent to Supreme Court approval, SVP laws have been adopted in 20 jurisdictions. Best estimates are that upward of 5,000 people, mostly men, are confined. Implementation varies widely among jurisdictions in areas such as per capita commitment rates (varying from 0.76 to 128.6 per million) and number of discharges (ranging from 1 or 2 to 185). Commentators estimate that the total cost of SVP programs in the United States approaches US\$1 billion each year. The average per capita cost for confinement, care, and treatment is about US\$95,000 for SVP programs compared with US\$26,000 for prisons.

Justifications and Critiques of SVP Laws

SVP laws remain highly controversial. In this section, the arguments for and against SVP laws are reviewed.

The strongest justification for SVP laws is that they demonstrably prevent at least some recidivist sexual violence. Critics argue that the cost of these programs is very high and that risk assessment is questionable. But supporters argue that the laws are justified even if only one horrendous crime is avoided. These policy makers assert that the United States should *spare no expense* in preventing the *next* horrific sexual crime.

Critics argue that this framework ignores costs, both monetary and moral, and that the SVP laws may engender. Critics argue that policy makers should ask whether the resources invested in SVP programs could prevent more crimes if allocated differently. SVP programs are focused on recidivist violence and, by design, on a small portion of recidivist violence. But recidivist crimes—that is, crimes that are committed by individuals who are released from criminal sentences for similar crimes—constitute a small percentage of all sex crimes. As well, recidivism rates for sex offenders are lower than many in the public estimate. A large meta-analysis involving 10 studies found recidivism of 14% at 5 years, 20% at 10 years, and 24% at 15 years after release from prison. Other studies found recidivism rates for rapists and child molesters to be about 5% after 3 years; some studies find recidivism rates even lower. There are authoritative studies that show that recidivism rates have declined since the late 1990s and that recidivism declines with age.

There are few empirical studies of the efficacy of SVP laws. A 2013 study of the Minnesota program estimated that Minnesota's program reduced the 4-year sexual recidivism rate in the state from 3.2% to 2.8%. A 2013 national study focused not on recidivism but on rates of sexual violence. It found no statistically significant correlation between SVP laws and the rate of sexual violence. Thus, a key question is whether the resources devoted to SVP programs could be more effective in combatting sexual violence if redirected. Critics suggest reframing the policy debate. Instead of asking whether SVP laws prevent some sexual

violence, the focus should be on asking how resources should be allocated to prevent the most violence. SVP laws are based on the theory that the best strategy is to spend relatively large resources on preventing a few *highly likely* crimes. The alternate approach suggests spreading the resources more broadly, addressing individuals who are individually lower risk but collectively account for a much greater percentage of sexual violence. Many violence prevention programs are underfunded, as are some supervision programs for released sex offenders and aspects of rape prosecution evidence collection.

An additional critique is that SVP laws invigorate a dangerous strand in U.S. law, which excludes *outsider* groups from full protection of the Constitution. Slavery and Jim Crow laws are obvious examples, but the reach of this exclusionary philosophy extends further, to forced sterilization of *imbeciles*, internment of U.S. citizens of Japanese descent, and the exclusion of gays and lesbians from equal participation in civic life. The Supreme Court's approval of same-sex marriage in 2015 seemed to signal the end of this sort of *outsider jurisprudence*. But SVP laws mandate a *reduced rights* zone based on who a person is rather than what a person has done. By claiming that some form of mental abnormality justifies the abrogation of hard-fought constitutional limitations on the power of the state, critics fear that these laws give extended life to the discredited outsider jurisprudence.

Critics argue that SVP laws distort the U.S. approach to sexual violence prevention in three ways. First, the laws distort society's view of sexual violence by suggesting that sexual violence—or at least the *worst* of it—is beyond the control of the men who commit it because it is *caused by* mental abnormality. But empirical findings establish that sexual violence is not aberrational, is mostly committed by acquaintances and intimates rather than strangers, and is facilitated by societal norms, myths, and attitudes more than mental disorder.

A second distortion that SVP laws strengthen is the public policy focus on recidivism as the core problem to be addressed in the fight against sexual violence. SVP laws are based on the premise that recidivism among sex offenders is extraordinarily high. Repeated frequently by courts, this

meme is false. Sex offenders have recidivism rates that are lower than many other categories of criminals; a majority of sex offenders are not apprehended for recidivist sex crimes.

But critics also claim that the focus on recidivist crime misdirects the public's attention. The great majority of sex crimes (some studies find 95%) are not recidivist crimes. They are crimes committed by offenders who have not been apprehended before for a sex crime. A focus on recidivism directs attention away from the great bulk of sexual violence and away from policies that address root causes of sexual violence.

Many commentators urge an alternate framework for combatting sexual violence. A public health approach would insist on a comprehensive and systematic set of policies, based on empirical knowledge, rigorous program assessment, and adoption of best practices. Interventions would aim at root causes (primary prevention) to attempt to head off violence before it occurs. These programs would be combined with standard criminal justice interventions as well. Resources would be allocated to program evaluation, disseminating and implementing models that prove successful.

Current Status

In 2018, SVP laws are well into their third decade. A second generation of legal challenges is now working its way through the courts. Two federal district courts have held that state programs are unconstitutional as they have been implemented. Several other cases are working their ways through the courts. But a federal appellate court reversed the first of the district court decisions. As of September 2018, the second is on appeal.

These cases present a number of challenges to the implementation of these laws. The most well-developed challenges focus on the states' failure to fulfill the requirement that SVP laws have the key characteristics of bona fide civil commitment programs. The trial courts have found that some SVP programs have a punitive purpose, in large measure, because states have failed to monitor ongoing risk, provide less restrictive alternatives in the community, and release committed individuals just as soon as the circumstances justifying confinement no longer obtain. In reversing, the appellate court held that the systemic failure to release to community settings did not violate the constitution.

SHOCK INCARCERATION

Shock incarceration (SI) is a correctional alternative to traditional incarceration that seeks to *shock* individuals convicted of crimes away from engaging in further criminal activity. The programs, also known as *correctional boot camps*, have a regime of military basic training-style discipline and rigorous physical activity as their centerpiece, which is often complemented by educational, counseling, and occupational training opportunities. SI programs, which are typically located in facilities that are separate from prisons or jails, allow individuals who successfully complete the program to serve less time than they would if sentenced to traditional prison or jail confinement. Originating in the early 1980s, SI programs marked an important innovation in corrections strategy, combining punitive and therapeutic interventions targeting individuals typically convicted of less serious criminal offenses seeking to shock them into behaving in a disciplined and respectful manner and away from additional involvement with the criminal justice system. This entry surveys the early history of SI programs, details of the correctional methods they employ, program goals, and research conducted on the effects of SI.

Early History

SI originated in the wake of two related innovations in corrections. The first was *Scared Straight*, a strategy targeting juvenile offenders who gained fame as the result of a documentary film released in 1978. The program was developed for at-risk juveniles who had engaged in antisocial activity but had not yet committed crimes that were worthy of longer term incarceration. As part of their *treatment*, individuals spent a brief period of time in a hostile prison environment, where they were exposed to verbal abuse from inmates and learned firsthand of the hardships of prison life, an experience designed to scare them away from engaging in criminal misconduct upon their release. The second innovation, Shock Probation, featured a 90- to 120-day program where an offender would be detained in the general prison population to get a true taste of prison life. After serving the 90- to

120-day term, the offender served the remainder of his or her sentence in the community on probation and would remain out of prison absent violation of his or her probation conditions.

SI debuted in 1983, first in Oklahoma and 1 month later in Georgia. Louisiana opened the first SI program targeting juveniles alone in 1985. SI gained popularity very quickly. Like other intermediate sanctions popular in the 1980s, it appealed both to policy makers favoring a *get tough* orientation, which did not coddle individuals, and those favoring rehabilitative treatment and programming. By 1995, states operated 75 programs for adults and 30 for juveniles, and counties operated 18 programs.

Program Details

To begin with, SI programs differ in their programmatic details. Typically modeled after military boot camps, SI programs emphasize discipline and obedience to authority. Participants address the correctional officers and other inmates by military titles, punishment for misbehavior comes in some form of physical activity, like pushups, and inmates and correctional officers alike wear military-style uniforms. Military drills and demanding physical training dominate, complemented by hard physical labor such as ditch digging, clearing land, and constructing walkways, all with hand tools to maximize physical effort among participants. Inmates must also undergo an entry ceremony and a head shaving requirement, stand at attention in drill lines, and participate in graduation ceremonies upon the successful completion of the program.

Along with programmatic details, programs also vary in their emphasis on rehabilitation. For instance, Illinois dedicates 3 hours a day to rehabilitation-related activities, with half of that time occupied by some form of counseling and the other half education. Elsewhere, such as in New York, participants spend up to 6 hr on such activities, including alcohol and drug counseling, vocational training, decision-making classes, and educational instruction.

In addition, SI programs contrast from one another in their eligibility criteria. Most often, with adult populations, participation is limited to young adults between the ages of 18 and 29 years, whereas

Louisiana allows participants up to the age of 39. Some states, such as Oklahoma, New York, and South Carolina, require that participants' offenses be nonviolent in nature, and most programs require that participants have not been previously incarcerated in prison; a minority of programs bar participation if an individual has been convicted of a felony. However, a few states, such as Florida, accept participants as long as their crime is not punishable by death or life imprisonment. Some states will only admit participants whose crime is only punishable by probation, while other states require maximum sentences not to exceed 5 years, and other states allow up to 10 years.

Finally, SI programs are distinguishable from one another in their duration. Some states, such as Georgia, have a 90-day program, while others, such as Missouri and Georgia, have a 120- and 180-day program, respectively.

A key commonality among the programs is that participants have an incentive to successfully complete program requirements because doing so provides sentence relief. Although programs vary, the most common result upon graduation from an SI program is release on parole or probation, whereby the offender will continue to be supervised by the corrections system. In New York, for instance, program graduates are reviewed by the parole board, which decides whether release on parole is warranted, which permits the individual to avoid serving their full sentence. Predictably, failure to complete the program carries adverse consequences—the individual faces detention in a traditional prison or jail where they will serve a much lengthier sentence—compared to what would have been the mere length of the particular SI program.

Goals

The chief goal of SI is crime reduction, and it seeks to do so by two principle means: deterrence and rehabilitation. As for deterrence, SI is considered more severe than serving a probation term in the community and less severe than long-term incarceration. Originally, SI programs were to be located in prisons but separate from general population. This view of prison from the inside, combined with physical activity, strict discipline, and hard labor, was designed to discourage future

criminal behavior. SI seeks rehabilitation in two ways. First, the strict discipline entailed in the program seeks to instill self-discipline in participants after the program and improve participants' self-esteem, self-control, and ability to handle stressful environments they might encounter in life outside. Second, while as noted programs can vary in their content, those emphasizing counseling and education do so to provide the tools needed to succeed in work and school after release.

SI is thought to have other benefits as well. Most important, SI can channel eligible offenders away from incarceration in prison and jail and result in shorter periods of detention overall, allowing jurisdictions to reduce corrections costs and reduce reliance on often already overcrowded institutions.

Research Results and Use

Over time, interest in SI waned in the United States. In significant part, this was due to research suggesting that SI did not secure the reductions in recidivism touted by advocates. Some studies found no benefit while others found a marginal reduction in recidivism, compared to regular forms of punishment, but that the reduction tended to diminish over time. In addition, some studies found that juveniles who participated in SI programs were more likely to commit future crimes more quickly than individuals in control groups. Although research reveals that SI programs succeed in instilling better skills, attitude, and behavior into participants, this success simply does not translate into a reduction in recidivism. Part of that failure can be described as a *low dosage problem*. Although a lofty goal, it is not realistic to expect a program that only spans 180 days at most to have such a large change in offenders who have had an antisocial lifestyle instilled in them over a span of years. Furthermore, there is no incarceration boot-camp model. Thus, an analysis of boot camps across different states shows a lack in consistency on how much programs focus on offender reentry into the community. This failure is reflected in the overall failure in reducing recidivism.

In addition, research indicated that SI programs are far too small on a national scale to have a major effect on the cost savings that were once expected. This is 2-fold: Firstly, there are not

enough SI programs to house a large enough amount of prisoners to create the savings that would be expected by reducing operation costs and construction costs of new jails and prisons. Secondly, SI programs require more staff than traditional incarceration facilities, and because SI programs provide much more rehabilitative services than traditional incarceration facilities, the negligible cost savings are negated.

Meanwhile, concern arose over the safety of the programs. In a Florida SI program, for instance, 14-year-old Martin Lee Anderson collapsed and eventually died after correctional officers tried to awaken him with smelling salts, which resulted in his suffocation. Anderson's death eventually resulted in Florida's ban on state-run boot camps in 2006.

In response, nationwide many states have ceased their SI programs. As of 2000, close to one third of state-run SI programs had closed, and total boot-camp population fell by over 30%. This trend continued, and it even extended to New York, a state that has long boasted prison boot camps. At one time, New York ran five SI programs; however, in 2011, the state closed two of its five boot camps, and another in 2013, leaving just two remaining programs. In addition, the Federal Bureau of Prison discontinued operation of its SI programs in 2005. As of 2017, the exact number of SI programs in operation is not recorded; however, the downward trend in SI leaves the impression that new programs will not be opened.

SHOPLIFTING

Shoplifting is defined as the theft of goods from a retailer and is a criminal activity that can encompass many different behaviors, such as from pocketing an item and leaving the store to consuming food products within the store and not paying the retailer. Just as there is a wide range of items that can be shoplifted, there is also a vast array of motivations and techniques for committing this crime. Although a formal measurement of shoplifting based on data at the national level is

minimal, the body of research on this offense suggests that it is a massive crime problem not only in the United States but also worldwide. Research on shoplifting from the 1950s to present has employed a wide range of methodologies in attempts to uncover the psychological and demographic characteristics of typical shoplifters, although some recent research, since 2015, has moved beyond focusing on individual offenders to highlighting typical shoplifting techniques in an effort to assist retail security personnel with the prevention of shoplifting. This entry provides an overview of the scope and cost of shoplifting, examines the psychology and demographics of shoplifters, and reviews research that focuses on shoplifting techniques.

Scope and Cost

According to the National Association of Shoplifting Prevention (2014), there are about 27 million shoplifters in the United States today. It is estimated that there are 550,000 daily incidents of shoplifting in the nation, which account for over 20 million shoplifting incidents per year, with an estimated yearly cost of about US\$17 billion in goods per year. However, these estimates are likely much lower than the actual scope and cost of shoplifting, due to the minimal measurement of shoplifting in national-level, longitudinal data sources.

Official data sources, such as the Federal Bureau of Investigation's annual *Uniform Crime Reports*, are able to convey only a small proportion of all shoplifting incidents. The true extent of shoplifting is underrepresented in this data source since it is based entirely on offenses known to law enforcement. Several complications arise when attempting to establish a valid and reliable estimate of shoplifting using the Uniform Crime Report. First, store personnel simply do not detect every incident of shoplifting. Second, shoplifters may intentionally target stores with low capabilities of detection. Third, retailers develop shoplifting policies at their own discretion, including the policy of not apprehending suspected shoplifters. Finally, detected incidents of shoplifting are unlikely to be reported to law enforcement if the dollar value of the stolen item is deemed insignificant.

Even with the caveat that the scope and cost of shoplifting are likely underestimated, available estimates nonetheless demonstrate that shoplifting should be a cause of concern for both retailers and consumers, in addition to social scientists interested in criminology and crime prevention. The lack of attention to shoplifting is potentially explained by surveys of consumers who regularly rate shoplifting as among the least serious crimes and who also tend to maintain antibusiness attitudes that may reduce their concerns for the troubles faced by retailers. Although retailers and crime prevention practitioners have a history of working together to develop and evaluate anti-shoplifting security measures, criminological interest in shoplifting mainly focuses on the crime as an expression of general delinquency or deviance. However, a large body of early (1950–1980) criminological research and theory was concerned with the development of psychological typologies of shoplifters.

Psychology

Incidents of shoplifting have been documented since the 1500s. However, it was not until the late 1800s that scholars, primarily those in the field of psychology, began focusing on this crime in attempts to explain what appeared as an unprecedented shoplifting epidemic among middle-class females. A great deal of research has since been devoted to understanding this trend alongside the changing nature of the retail market and women's greater access to goods; though, at the time of this so-called shoplifting epidemic, scholars instead focused on *kleptomania* and the underlying causes of this irrational behavior. Female kleptomania was most frequently understood as resulting from myriad sexual problems, including menopause, irregular menstruation, and unfulfilled sexual desires.

As indicated by the previous explanation of female kleptomania, early research (1920s–1980s) on shoplifting was dominated by the Freudian perspective of psychology. This perspective was not limited to female shoplifters but was extended to all shoplifters, regardless of age or gender, although the specifics concerning offenders' psychological and physical pathologies differed

accordingly. Psychological profiles and typologies were created to aid in the understanding and the categorization of shoplifters and their motivations. To develop their profiles and typologies, psychologists typically made use of samples of apprehended shoplifters that were referred to them by the court. As such, research on shoplifting in this time frame primarily concerned those who would now be considered atypical shoplifters (e.g., the psychologically disturbed or the elderly).

Modern scholars continue to maintain an interest in psychological explanations of shoplifting. However, since the 1980s, social scientists have sought to situate shoplifting within a larger structure of delinquent or deviant behaviors. Rather than explaining shoplifting as mentally disturbed kleptomania, researchers attempt to understand the psychology behind delinquency and deviance more generally, of which shoplifting appears to be only one of many potential expressions. This is a fruitful development in the body of research on shoplifting, particularly since past studies have consistently shown that the psychological and personality characteristics of shoplifters do not differ significantly from those of their nonshoplifting counterparts.

Demographics

In addition to generating a better understanding of the psychology of shoplifters, scholars also have worked toward developing a demographic profile of the typical shoplifter. Initial attempts to achieve this goal, in the 1960s and early 1970s, involved the use of store apprehension data. Store records offer researchers a number of benefits beyond those of police records. Store apprehension data may be more accurate than law enforcement data since store records include both offenders who were apprehended by store personnel but were not brought to the attention of law enforcement as well as those that were referred to the criminal justice system. This allowed researchers to examine the demographic and crime-specific similarities and differences among offenders who were referred to the criminal justice system and those who were not as well as differences in how store personnel handled apprehended shoplifters.

Store records also offered a more complete picture of shoplifters' demographic characteristics as well as the characteristics of typical stolen goods, such as their types and values.

The use of store records represented a pivotal first step in the attempt to develop an accurate representation of contemporary shoplifting trends. Regardless, this methodology has a number of drawbacks. First, store records contain more information than that collected in the Uniform Crime Report, but they are not exhaustive. They do not offer insight into shoplifters' criminal motivations, prior criminal histories, social class, or economic status, to name a few relevant criminological characteristics. Second, since there is variability among retailers' abilities or policies in the apprehension of shoplifters, it is arguable that any store's apprehension data are more likely a reflection of that store's security practices than of average shoplifters. Third, the generalizability of store apprehension data is questionable since it is unlikely that findings about the typical shoplifter in a boutique-style store, for example, could be extrapolated to shoplifters of department store or grocery chains, and vice versa.

Other attempts to develop a more accurate demographic profile of shoplifters have overcome many of the drawbacks of the use of store apprehension data. Some scholars have made use of observational studies, in which the researchers covertly observe shoppers to differentiate regular shoppers from shoplifters. Such covert observation has aided in the development of the sociodemographic profile of typical shoplifters in the type of store in which the study has taken place and also has provided information about telltale behavioral cues that may aid security personnel in being alerted to potential shoplifting activity. Observational data have led to important advances in the improvement of demographic and behavioral profiles of shoplifters. However, researchers making use of this methodology have taken care to note that observations of shoplifting are at risk of being driven by the preexisting biases of observers.

Self-report data also represent a significant improvement in the accuracy of shoplifting profiles. Findings from one national-level longitudinal study, *Monitoring the Future*, established that the

body of shoplifters is comprised of both males and females, from all races and ethnicities, and from a wide range of age groups. An additional insight from this study includes the finding that shoplifting activity tends to peak during adolescence and then declines between the ages of 17 and 23 years. This is supportive of findings from other self-report surveys, which indicate that shoplifting generally corresponds to the age-crime curve prevalent among most other forms of crime.

Altogether, despite their various limitations, research on the demographic characteristics of shoplifters using store report, observational, and self-report methods has provided a great deal of information about the typical shoplifter and the typical shoplifting incident. In turn, this body of research has helped dispel many of the stereotypes about shoplifting (e.g., shoplifters are mentally disturbed or should be classified as kleptomaniacs) that arose as a result of early attempts to develop psychological profiles and typologies of shoplifters. More importantly, such research has begun to dispel the idea that shoplifting is a pink-collar crime (i.e., a crime dominated by women). A vast array of studies representing each of these methodologies has consistently shown that women rarely represent more than half of any sample of shoplifters.

Research Focus: Techniques

Much research on shoplifters since the 1980s has been conducted with the goal of uncovering the sociodemographic characteristics of the typical shoplifters. However, results indicate that everyone is a potential shoplifter, regardless of gender, race, age, or status. Rather than abandoning shoplifting as an important area of criminological inquiry, a more recent research by Lasky et al. (2015) has instead focused on delineating the techniques and decision-making of shoplifters, with the goal of assisting store security personnel in attempts to prevent shoplifting and to reduce the harms caused by shoplifting to both retailers and consumers.

Researchers have employed several different methods to more closely examine shoplifters' techniques. Among these are observational studies, discussed previously, which have provided

important information on telltale behavioral cues exhibited by shoplifters before, during, and following the theft of an item. Additional studies have made use of a qualitative elaboration on self-report data, in which shoplifters narrate their decision-making processes after forming an intention to steal while walking through a store. Data from these studies aid in distinguishing between degrees of shoplifting expertise, perceptions of effective deterrents, and the influence of store layout on the likelihood of engaging in shoplifting after the shoplifter acknowledges an intention to steal. In a recent development of shoplifting research, an eye-tracking device has been used to record shoplifting from offenders' perspectives, alongside shoplifters' narration of the resultant video data, which together provide insight into concealment techniques, impressions of store security, and decision-making processes at each stage of the shoplifting event. Overall, research focusing on the techniques of shoplifters has moved beyond the simple classification schemes of initial shoplifting studies, and the impasse of sociodemographic profiling, to assist retailers in reducing shoplifting as well as to reduce the likelihood of individuals to engage in the crime of shoplifting.

SHORT-TERM ASSESSMENT OF RISK AND TREATABILITY (START)

The START is a succinct structured professional judgment guide for the assessment of dynamic vulnerabilities and strengths associated with risk of violence, self-harm, suicide, unauthorized leave, substance abuse, self-neglect, and being victimized by others. Working with individuals in criminal justice, psychiatric, and community mental health contexts calls for practitioners to identify the risks that individuals might pose to themselves or others (e.g., violence, suicide, nonsuicidal self-injury) and to effect management plans to prevent undesirable outcomes (e.g., mental illness relapse, rehospitalization, violence, recidivism, substance use relapse, suicide, self-harm). Given the pervasive risks to self and others in these populations and the substantial personal and social burdens, risk assessment is a process with inherently high stakes. It is fraught with challenges, including the potential for liability risk and ethical issues for the assessor, reduced civil liberties for the individual, stigma for the population, and economic implications and safety concerns for the public. Considerable investment has been made in exacting how best to conduct risk assessments and to translate those findings into effective risk management plans. The START is one such endeavor.

The START has been recognized by several agencies (e.g., Accreditation Canada, UK Department of

Health) and experts as a promising, leading, or best practice in the assessment and management of violence and related risks. It is being used across the globe in correctional, forensic, and mental health institutions and community programs. As of 2018, there were nine language translations (Danish, Dutch, Finnish, French, German, Norwegian, Spanish, Swedish, and Thai; with Italian, Japanese, and Russian translations in preparation) and more than 50 published articles on the START. There also is a version for use with youth aged 13–18 years, the START: Adolescent Version.

This entry begins by discussing the development, key characteristics, and use of the START; then the entry focuses on the research evidence for the START.

Development and Key Characteristics

The START was developed in the early 2000s in direct response to limitations of existing risk assessment measures, as identified in the research literature and by direct care providers and clinicians. The START is unique compared to other risk assessment measures because of several key characteristics, including its focus on dynamic factors, strengths and vulnerabilities, and multiple short-term adverse outcomes.

Dynamic Factors

START assessments focus on an individual's current functioning on dynamic factors, within the context of their history. Historical, static factors (i.e., unchangeable variables, such as a history of child abuse, criminal record) and stable factors (i.e., variables that can change but that often are difficult or slow to change, such as antisocial attitudes) provide essential insights into future behavior and effective risk management endeavors. However, research also demonstrates the value of dynamic factors (i.e., changeable variables, such as social support), particularly in imminent, acute, and short-term assessments. Moreover, good clinical and criminal justice practice demands that assessors are attentive not only to factors that increase risk but also those that can be changed through intervention.

Strengths and Vulnerabilities

The START acknowledges that clients have strengths and vulnerabilities that can coexist and that interact with each other. The START thus guides assessors to evaluate an individual's vulnerabilities (i.e., risk factors) as well as their strengths (i.e., protective factors). Prior to the development of the START, several well-respected scientist-practitioners in clinical risk assessment lamented that the field had failed to integrate balanced risk assessments. This is akin to a financial planner only asking about a client's debts and not taking into account the client's savings and investments. There are many potential advantages to considering an individual's capacities, positive assets, and skills in addition to their challenges when assessing risk. Specifically, talking to an individual about his or her strengths can help bolster the individual's sense of self and foster motivation and engagement, contributing to improvements in clinical outcomes and, ultimately, reductions in risk. Strengths also can be embedded in the risk management and treatment plans, providing opportunities to maintain and enhance current strengths and identify what might have fostered prior periods of stability and success (e.g., residing with a supportive family member or partner). Identification and use of strengths is also an inherent part of trauma-informed care and a recovery-oriented approach. Finally, research supports the unique contributions of protective factors to the prediction of adverse outcomes, above and beyond risk factors.

Comprehensive Care

Planning: Multiple Adverse Outcomes

The START guides assessors to estimate risk of diverse health and safety concerns that are found across the populations served by social, criminal justice, and mental health agencies, with the goal of informing comprehensive care planning. Marginalized and high-risk populations experience elevated rates of violence, suicide, self-harm, substance abuse, self-neglect, unauthorized absence, and being victimized by others. Frequently, these individuals present with several of these challenges over the course of their lifetime or at any one time. Research demonstrates, for instance, that individuals with mental illnesses are at greater risk of being violently victimized than they are of

committing violence. As such, a comprehensive intervention strategy may be most effective in reducing risk across multiple domains.

Integrated Assessment, Management, and Treatment

Built on a combination of historical information and dynamic factors, the START integrates risk assessment with risk management and intervention. Practitioners (e.g., probation officers, case managers, nurses, psychologists, psychiatrists) can remain attentive to an individual's persistent risk state, while *tuning up* management plans and interventions to best match the individual's current needs. To demonstrate, as a baseline, an individual with a history of suicide will be considered to be at greater risk of future suicide than an individual without a history of suicide. However, if the suicide attempt was 15 years ago when the individual was a teen, the attempt was more of a gesture (e.g., low lethality, while his parents were home, following a breakup with his first girlfriend), the individual has not had suicidal ideation since, denies experiencing relevant thoughts, plans or affect, and is presently happily married, then the suicide risk would be considered low.

Repeated Assessments

Reflecting the focus on dynamic factors, the START is intended to be completed every 2–3 months to document change in psychosocial functioning and safety and to inform revisions to the management and treatment plans, if any. When there is evidence or anticipation of acute risk, the START should be repeated more frequently. In addition, deterioration or substantial improvement in mental state or situational circumstances could prompt more frequent reevaluation. In the previous example, if during a subsequent discussion, the client reported that his wife was divorcing him and he was feeling depressed, had passing thoughts of suicide, but had no current intention or plans, his risk of suicide would increase to moderate, at a minimum. In addition, the practitioner may consider a more in-depth suicide assessment and follow-up.

The objective of hospitalization, probation, and treatment is to prevent undesirable outcomes (e.g., rehospitalization, recidivism, substance abuse

relapse, loss to treatment) and to bring about positive improvements in the individual's mental health and well-being. Most hospitalized patients and inmates eventually return to the community, and consistent with community-based care being the preferred mode of mental health service, it is generally expected that individuals will transition through the continuum of care. As such, a measure like the START that demonstrates therapeutic progress or deteriorations is essential. In this way, the START is also highly useful for treatment evaluation research.

Description and Use

The START comprises 20 items: Social Skills, Relationships, Occupational, Recreational, Self-Care, Mental State, Emotional State, Substance Use, Impulse Control, External Triggers, Social Support, Material Resources, Attitudes, Medication Adherence, Rule Adherence, Conduct, Insight, Plans, Coping, and Treatability), each coded for both Strength and Vulnerability and for its historical relevance to safety and well-being. Specifically, Key Items are used to identify strengths that have been known to buffer risk or may act as a therapeutic lever, whereas Critical Items are used to identify vulnerabilities that have previously triggered a cycle of decompensation and increased risk. To demonstrate, an individual may have pro-social family support and may also socialize with antisocial peers; thus, the START assessor would code the presence of both strengths and vulnerabilities on the Social Support item. Assessors also are prompted to identify a specific set of symptoms and signs that are unique to the individual and may be seemingly unrelated but reliably are associated with increased risk of harm to self or others, called *Signature Risk Signs*.

The START was developed in the structured professional judgment tradition, meaning that assessors do not use numeric algorithms or cut scores to inform their final risk judgments. Instead, assessors estimate risk over the next 3 months for the seven outcomes (i.e., violence, suicide, self-harm, substance abuse, self-neglect, unauthorized absence, and victimization) as low, moderate, or high through consideration of Strengths and Vulnerabilities ratings, Key and Critical Items, Signature Risk Signs, and history of each of the outcomes. Once areas of elevated risk are

identified, the START, in the section on Risk Formulation, guides assessors to describe the specific factors that predict or explain how, when, and against whom these risks become elevated. The START assessment is then used as the blueprint for a comprehensive risk management and integrated treatment plan.

Although the focus of the START is on recent and current functioning, assessors integrate past and present information to inform their risk assessments. Specifically, the Strength and Vulnerability ratings on each of the 20 dynamic factors are based on the individual's functioning in the past 2–3 months or since the last START assessment. Past and present information is used to code Key and Critical Items and Signature Risk Signs and to identify history of the risk domains.

START is intended to support professionals working with diverse populations (e.g., homeless individuals, civil and forensic psychiatric patients, probation clients). User qualifications do not require that assessors hold a PhD or MD; however, several items require expertise and experience in mental health. Completion of START assessments within the context of a treatment or case management team is highly encouraged, though completion of START assessments by individual practitioners is common.

Research Evidence

Research on the START has demonstrated good to excellent interrater reliability, moderate concurrent validity, and effect sizes for predictive validity, generally in the moderate to large range. Specific Risk Estimates have demonstrated incremental validity over Vulnerabilities and Strengths items for aggression, self-harm, suicidality, and victimization, while research on user acceptance reports high rates for clinical as well as risk management utility.

Interrater Reliability

Several studies have evaluated the interrater reliability of START assessments. Generally, mean intraclass correlation coefficients are in the good to excellent range for the vulnerability, strength, and risk estimates. Researchers and clinicians also have good concordance, as do mental health professionals from diverse disciplines (e.g., nursing, psychiatry, social work).

Agreement on Key Items and Critical Items is less consistent; research to date also suggests that it may vary by profession.

Concurrent Validity

Researchers have examined the association between the START and the Psychopathy Checklist–Revised, the Historical-Clinical-Risk Management-20, the Suicide Risk Assessment and Management Manual, and the Level of Service Inventory–Revised and found START assessments to correlate with assessments completed using other measures in the expected manner. For instance, moderate positive correlations of the START Vulnerability total scores and moderate negative correlations of the START Strength total scores with Psychopathy Checklist–Revised and Historical-Clinical-Risk Management-20 total scores have been observed.

Predictive Validity

To date, the majority of published studies on START assessments have focused on the prediction of violence risk. The majority of studies demonstrate a significant association between inpatient aggression of various forms (e.g., any, verbal, physical) and both Vulnerability and Strength total scores; however, the association for strengths is less consistent in the research. These effect sizes are generally in the moderate to large range and are highly consistent with meta-analyses in the field. Predictive validity for the other six risk domains is promising, but variable, and studied less frequently. There is also emerging evidence of validity in predicting general offending.

Incremental Validity

Specific Risk Estimates have demonstrated incremental validity over Vulnerabilities and Strengths items for outcomes such as aggression, self-harm, suicidality, and victimization; that is, a low, moderate, or high rating on the seven risk estimates is a better predictor of adverse outcomes than simply summing up the item scores. In addition, Strength total scores have demonstrated incremental validity over the Vulnerability total scores in the prediction of aggression and general

offending, although this finding is less consistent and requires further study.

Change and Distribution of Scores

Research demonstrates that when the START is administered repeatedly over time, changes are evident in Strength and Vulnerability total scores, as well as the Specific Risk Estimates, that correspond to changes in security needs and that can be monitored and evaluated in association with targeted interventions. This means that on average, patients' Strength scores increase and their Vulnerability scores decrease as they move through the continuum of care—from locked/secure units to medium-security units and eventually to minimum security units. Moreover, even within high-risk populations, START assessments have excellent dispersion. For example, in forensic psychiatric inpatients and community-based offenders, a reasonably normal curve on both Strength and Vulnerability total scores and a good distribution across risk estimate ratings (i.e., low, moderate, or high risk) have been demonstrated. Despite sharing many demographic (e.g., male, age) and static risk factors (e.g., a history criminal offending, violence, lengthy psychiatric histories), a small proportion of individuals have very low or very high Vulnerabilities and a small proportion of individuals have very high Strengths and very low Strengths.

Perceived Utility and User Feedback

Feedback from assessors provides strong support for the perceived utility of the START in practice. Several studies have shown that assessors find the START easy to use and informative for conceptualizing short-term risks and needs. Research also demonstrates that among those using multiple risk assessment measures, START is often ranked most highly.

SHORT-TERM ASSESSMENT OF RISK AND TREATABILITY: ADOLESCENT VERSION (START: AV)

The START:AV is a structured risk assessment tool designed to assess and manage short-term (i.e., 3 months) risk of multiple adverse outcomes among male and female adolescents in mental health and/or criminal justice settings. Adverse outcomes included within the START:AV are categorized into two broad domains: *Harm to Others and Rule Violations* (i.e., violence, nonviolent offenses, substance abuse, and unauthorized absences) and *Harm to the Adolescent* (i.e., suicide, nonsuicidal self-injury, victimization, and health neglect). The START:AV adheres to the structured professional judgment model of risk assessment and is an adapted version of the Short-Term Assessment of Risk and Treatability designed for use with adult psychiatric populations. The START:AV is relevant to correctional psychology, as it not only helps to guide the assessment and management of risk of violent and nonviolent offending but also provides a comprehensive assessment of other adverse outcomes that are considered critical to an adolescent offender's well-being. The current entry describes the START:AV and discusses its purpose and development and provides a brief overview of the empirical findings regarding its reliability and validity.

Description and Purpose of the START:AV

The START:AV comprises 25 items, 24 of which fall into three clusters: Individual Adolescent, Relationships and Environment, and Response to Interventions (see Table 1 for a list of the items by cluster). Embedded within the START:AV is an additional case-specific item (i.e., Item 25) that

23. Medication Adherence
24. Treatability

allows for the assessor to incorporate any information pertinent to the assessment that is not otherwise captured by the other 24 items (e.g., culture). All items of the START:AV are considered modifiable (i.e., dynamic in nature), and unlike other contemporary risk assessment tools such as the Structured Assessment of Violence Risk in Youth, the START:AV does not separate items

based on whether they are risk or protective factors; rather, each item is simultaneously rated as both a Strength (i.e., a feature or characteristic that decreases risk of an adverse outcome) and a Vulnerability (i.e., a feature or characteristic that increases risk of an adverse outcome). For example, an adolescent can display both strengths and vulnerabilities within a single area such as a youth who primarily associates with antisocial peers, yet maintains contact with some prosocial peers (e.g., Item 17: Peers). As such, ratings of Strengths and Vulnerabilities may or may not correspond with each other. Each item is rated as *low*, *moderate*, or *high* based on whether an adolescent has displayed minimal, some, or substantial Strengths or Vulnerabilities within a specific area over the past 3 months. In rating the items, assessors are to use adolescents who are of a similar age in the general population as a reference for comparison.

After each individual item is rated, Key Strengths (i.e., items that are considered to be instrumental in decreasing or buffering a youth's risk) and Critical Vulnerabilities (i.e., items that are considered to be instrumental in increasing or driving a youth's risk) are identified. However, not every Strength or Vulnerability rated as high need be identified as a Key Strength or Critical Vulnerability, respectively. Moreover, items rated as low or moderate may be considered a Key Strength or Critical Vulnerability as long as the item is judged as playing an instrumental role in a youth's risk of an adverse outcome. Before rendering a final risk estimate for the various adverse outcomes, assessors are to rate whether a youth has experienced an adverse outcome at any time prior to the past 3 months (i.e., Prior History) or within the past 3 months (i.e., Recent History). In adherence with the principles of structured professional judgment, the final risk estimate is not based on any total score or algorithm; rather, the assessor rates the adolescent's short-term risk by incorporating information gathered through the START:AV assessment in combination with his or her own professional judgment. In addition, assessors can include an additional case-specific adverse outcome that is not better addressed by the remaining eight adverse outcomes outlined within the START:AV manual (e.g., homelessness, prostitution).

Lastly, assessors have the option of flagging whether or not the youth poses an imminent risk of serious harm to themselves or others and requires immediate action. This is referred to within the START:AV manual as *T.H.R.E.A.T.*, an acronym that stands for *threat of harm that is real, enactable, acute, and targeted*. Assessors are encouraged to determine whether a T.H.R.E.A.T. is present or absent for four of the adverse outcomes (i.e., violence, suicide, nonsuicidal self-injury, and victimization). Upon completion of the START:AV, the assessor is encouraged to use the information gathered to inform intervention planning through risk formulation and identification of risk-related scenarios. To assist in monitoring treatment response and changes in risk level or risk-related scenarios (particularly if a youth experiences a major life event), it is recommended that reassessment with the START:AV be conducted at least every 3 months.

Development of the START:AV

Development of the START:AV was achieved through a multistep process. First was the establishment of a core team of researchers and clinicians with expertise in adolescent populations (including authors of the START) in conjunction with consultation with other professionals and experts in the field. Second, a review of the literature was undertaken to determine whether an adolescent version of the START would address various gaps in adolescent risk assessment. Third, the developers of the START:AV established a set of developmentally informed principles to guide the adaptation of the START to adolescent populations by reviewing the developmental psychopathology and criminology literature and approaches taken by other test developers. Fourth, each of the START items was reviewed to determine whether they had demonstrated empirical support in adolescent populations of which all items were found to have support. Fifth, while the START:AV retained all of the original items of the START, several important changes were made to ensure that items were developmentally relevant. This included adjustments to item anchors, revisions to coding instructions to account for the ways in which risk and protective factors manifest in

adolescents, introduction of new items (i.e., Parenting and Parental Functioning), and splitting of other items into subitems to emphasize the relationships that adolescents have with their peers and caretakers (i.e., Relationships and Social Support). Moreover, nonviolent offending was added as an adverse outcome given the overlap between risk factors with violent offending, and adverse outcomes such as victimization were revised to account for abuse perpetrated both by peers and adults (e.g., caretakers). Further development of the START:AV consisted of pilot implementation and testing of an earlier iteration of the tool in Canada, the United States, and the United Kingdom.

Reliability and Validity of the START:AV

Although there is a limited amount of research examining the START:AV, much of the research on the START:AV has been conducted using mixed samples of male and female adolescent offenders and forensic psychiatric patients, and preliminary findings are promising regarding its reliability and validity. Despite a final risk score not being produced in practice, much of the research conducted with the START:AV has used total scores derived by summing the items to produce a Strength and Vulnerability total score. With respect to reliability, the START:AV (including an earlier iteration of the tool) has demonstrated high internal consistency among the Strength and Vulnerability total scores. Likewise, there has been good to excellent interrater agreement across the Strength and Vulnerability total scores and structured risk estimates, although the level of interrater agreement has typically been higher among the total scores.

Moreover, the START:AV has demonstrated strong concurrent validity with other established risk assessment tools such as the Structured Assessment of Violence Risk in Youth, and the associations between risk and protective factors and Vulnerability and Strength total scores have been within the expected directions. With respect to predictive validity, the START:AV has shown significant predictive utility across shorter term (i.e., 3 months) and longer term (i.e., 3 years) follow-up periods in predicting multiple adverse

outcomes (e.g., violence, any offending, substance use, street drug use, any victimization, and nonsuicidal self-injury). However, while the various structured risk estimates and Vulnerability total score have generally demonstrated moderate to large associations with outcome, results for the Strength total score have been somewhat mixed.

In addition, research has demonstrated that items on the START:AV can reliably change over time, thus providing support for their dynamic nature. There is some evidence for the utility of the START:AV in risk management. In particular, one study found that when interventions targeted youths' Critical Vulnerabilities and leveraged youths' Key Strengths, the occurrence of externalizing behaviors such as aggression was reduced. However, despite this preliminary support for the START:AV, there is need for further research, particularly on its utility in managing risk and its relevance across gender and across ethnic, racial, and cultural groups.

Final Thoughts

Given its focus on strengths and vulnerabilities, the reassessment of dynamic risk, short-term prediction, and multiple adverse outcomes, the START:AV is a unique addition to the adolescent risk assessment and risk management field. As adolescent offenders not only can pose a risk of harm to others (e.g., violence) but also are vulnerable to being harmed themselves (e.g., victimization, suicide), the START:AV aims to provide an integrated assessment of multiple adverse outcomes that are relevant to adolescent offenders. While further research is needed, preliminary findings are promising and interest in the tool continues to increase. Moreover, several accompanying resources are available to users of the START:AV, such as the *START:AV Annotated Bibliography*, which provides an up-to-date overview of published and unpublished research conducted with the tool, and the *START:AV Knowledge Guide*, which provides a comprehensive review of the empirical research for each of the individual items.

SHOWUP IDENTIFICATIONS

Showup identifications, or showups (also known as *field identifications* and *one-on-ones*), involve the presentation of a single suspect to a witness of a crime for purposes of identification. Although included with police lineups as a manner for conducting identification tests, showups serve a unique purpose in the course of a criminal investigation. Since they normally occur shortly after the crime when a suspect is found close to the crime location, showups are often used to screen potential suspects before other evidence is available. They serve to generate probable cause for arrest of the identified suspect and to discourage pursuit of false leads when the witness does not identify the suspect. Although showups have a unique investigative value, showup identifications are less reliable than those obtained from proper police lineups. This entry discusses the legal and psychological perspectives of showups, as well as other relevant issues, and reviews recommendations developed by psychological scientists for conducting showup investigations.

Legal Perspectives on Showup Identifications

Showups are a commonly used identification procedure in the United States. The frequency of use of showups varies widely, with some agencies being much more likely to use showups than police lineups and others being more likely to use photographic lineups than showups. Estimates of their prevalence across U.S. law enforcement agencies range from 32% to 76% of all identification procedures. Data from the United Kingdom also support the prevalence of showup identification procedures in criminal investigations, with showups being used in over 70% of criminal investigations in which any identification procedure was conducted.

The widespread use of showups is a product of the unique investigative function they serve in comparison to other identification procedures. Showups are typically conducted early in an investigation when extrinsic evidence linking the suspect to the crime has often not been identified. This leaves a situation in which investigators do not have probable cause to initiate an arrest. A positive identification from a showup can provide investigators with the probable cause necessary to make an arrest and promote public safety by removing the potential perpetrator from the community. In addition, an accurate nonidentification from the showup can help ensure that the investigation does not get derailed by pursuing false leads.

The constitutionality of using of showups in criminal investigations has been determined through numerous U.S. court rulings (e.g., *Perry v. New Hampshire*, *Stovall v. Denno*, *United States v. Funches*). This case law is consistent in finding that showups are inherently suggestive procedures and should not be used when the opportunity exists to use a proper police lineup. However, the consensus across these opinions is that showups are not *unduly suggestive* and the benefit of an immediate identification test outweighs any harm caused by this inherent suggestiveness. As a result, although deemed to be more suggestive than lineups, showups are deemed to be permissible identification procedures.

Psychological Perspectives on Showup Identifications

Court rulings claim that showups are more suggestive identification procedures due to two factors. First, the presentation of a single suspect to witnesses, rather than presenting the suspect among a group of *fillers*, provides that suspect with no protection from a witness who feels compelled to identify someone. Second, the presentation of a suspect in police custody, often-times detained by law enforcement officers at the scene of the crime, is perceived to increase the suggestiveness. Although the body of literature in this area is small in comparison to that conducted on other identification procedures (i.e., police lineups), psychological scientists have found evidence supporting these claims.

Lack of Protection

Most research on showups has investigated the *lack of protection* concern by comparing showups with police lineups. Research conducted from the 1980s through the early 2000s produced mixed results with some studies finding that showups produced less accurate decisions compared with lineups and others finding no difference in accuracy across the procedures. A 2003 meta-analysis of these studies suggested that the lack of protection afforded by showups may not be problematic as showups generally performed similarly to lineups when comparing correct and false suspect identifications. However, there was some evidence that showups may produce more false identifications of innocent suspects that look similar to the actual perpetrator. A 2009 reevaluation of the findings of this meta-analysis questioned the earlier interpretation and suggested that showups, in fact, produced more false identifications of innocent suspects. Research conducted through the 2000s did not produce strong evidence that the lack of protection of showups negatively affected the accuracy of the witnesses' decisions. However, more recent research published in the early 2010s using more sensitive statistical techniques produced stronger evidence of the problems with this lack of protection, demonstrating that showups produce less accurate decisions than lineups, even if the lineups are poorly constructed and presented as much as 48 hr after the crime.

Custodial Influence

A concern routinely expressed in U.S. court decisions and among legal and scientific scholars is that the presentation of a suspect in police custody suggests to the witness that this individual is the likely perpetrator. There is very little psychological research that addresses this concern. Although some research has found that the presentation of an individual in police custody increases the witness's perception of the likely guilt of the suspect, no published research has investigated this impact on witness identifications in showups. One unpublished study evaluated this and found that this type of presentation increases the likelihood of the witness identifying the suspect as the perpetrator regardless of whether or not she or he actually committed the crime.

Other Issues Relating to Showup Identifications

In addition to evaluating the inherent suggestiveness of showups, as compared to police lineups, psychological scientists have investigated other factors that relate to the validity of identifications obtained through this procedure. However, the body of research on each of these factors is very small, so caution is warranted when drawing conclusions.

Clothing Bias

Individuals are typically identified as possible suspects to be placed in showups when they match the physical description of the perpetrator and are found in close proximity to the scene of the crime. Factors used to determine whether or not someone may be a suspect include not only the extent to which the suspect matches the physical characteristics of the perpetrator (i.e., age, gender, ethnicity) but also whether or not she or he is wearing similar clothing to that described of the perpetrator. Psychological scientists have evaluated the extent to which the presentation of a suspect in clothing similar to that worn by the perpetrator influences the accuracy of witness decisions in showups. Research conducted in the 1990s and 2000s identified that the presentation of innocent suspects in clothing similar to that of the perpetrator increased the likelihood of a false identification; however, this was only likely if the suspect and perpetrator were wearing distinctive clothing. Clothing bias did not occur when the suspect and perpetrator were wearing generic clothing (e.g., a plain T-shirt and jeans). However, research conducted in the 2010s has challenged the assumption that clothing bias harms the accuracy of showup decisions and suggests that it may actually improve witness accuracy.

Iterative Showups

Showups are typically used early in an investigation when law enforcement does not have much evidence indicating the identity of the perpetrator. Consequently, the same witness may participate in multiple showups during which they are shown a series of individuals to identify whether any of them are the perpetrator. For example, an officer

may detain two individuals that fit the description of the perpetrator and were found in close proximity to the crime scene. The officer may then show one of the individuals to the witness for identification purposes. If the witness positively identifies that individual, an arrest is typically made, and the second individual is released. However, if the witness indicates that the first individual is not the perpetrator, the officer may then show the second individual to the witness in a separate showup procedure. One published study has investigated the use of iterative showups and found that the likelihood of a false identification increases in the subsequent showup procedures.

Repeated Procedures

As showups are typically viewed as more suggestive than police lineups, many agencies routinely follow showup identifications with a lineup containing the same suspect. When there are multiple witnesses to a crime and the lineup is used for additional witnesses who did not initially participate in a showup, follow-up lineups can provide important information regarding the likelihood that the suspect is the perpetrator. However, when these follow-up police lineups are used with witnesses who already viewed the suspect in a showup, the probative value of subsequent identifications is significantly reduced. This reduction in the value of these follow-up lineup suspect identifications is caused by the increased likelihood that a witness will identify the suspect in the subsequent lineup simply because she or he viewed the suspect in the prior showup regardless of whether or not that suspect is the perpetrator. Furthermore, the repeated presentation of an innocent suspect across identification procedures can actually alter the witnesses' memory for the true perpetrator making it difficult for them to identify the true perpetrator even when encountering with her or him in the future.

Age of the Witness

There are very few studies examining the effects of witness age on identification decisions in showups. This limited research suggests, though, that the witness's age can influence the identification decision made when viewing a showup. Young

children (under 8 years of age) are more likely to identify a suspect in a showup regardless of whether that suspect is or is not the perpetrator. As a result, young children produce both more correct identifications when the suspect is the perpetrator and more false identifications when the suspect is innocent. Older children (ages 8–15) are more likely than adults to falsely identify an innocent suspect. Performance in showups does not differ across adulthood with young adults and the older adults performing similarly when making showup identification decisions.

Witness Intoxication

As showups are conducted shortly after the crime occurred, there is an increased likelihood of a witness being intoxicated while participating in a showup as compared to a police lineup that typically occurs days later. Few studies have investigated the influence of intoxication on witness performance in identification procedures. Only one published study has investigated the effects of intoxication on witness decisions in showups and found that intoxication increased the likelihood of a false identification. The remaining research focusing on police lineups has found no influence of intoxication on witness decisions, although some studies have found that intoxicated witnesses are less confident in their decisions.

Recommendations for Conducting Showup Identifications

Showup identification procedures are important tools for law enforcement in the early phases of a criminal investigation as they afford the investigators the ability to quickly exclude innocent suspects and develop probable cause for the arrest of a potentially guilty perpetrator. As a result, although psychological research suggests that showups provide less useful information than police lineups, it is unlikely that law enforcement will cease using showups in their investigative practices. However, psychological scientists have developed recommendations for how and when showup identifications should be used. Generally speaking, these recommendations are that police lineups should be the preferred identification procedure and that showups should be avoided when

it is possible to conduct a proper police lineup within a short time period. In addition, if a showup is deemed necessary, every effort should be taken to reduce the suggestiveness of the procedure by minimizing the presentation of the suspect in police custody (e.g., handcuffed, seated in patrol car) unless these efforts are necessary for police, suspect, and public safety. The witness should have a view of the suspect undegraded by distance, poor illumination, and reflection on glass surfaces between the witness and the suspect. If there are multiple witnesses, they should be separated before participating in any identification procedure and probable cause for an arrest should be obtained through the positive identification of a single witness viewing a showup with additional witnesses being shown proper police lineups at a later point in time. Furthermore, witnesses participating in a showup should not be shown any further identification procedures for the same suspect.

SICILIAN MAFIA

The Sicilian Mafia is a translocal fraternal organization whose respective local *families* called *cosche* (singular, *cosca*) lay claim to rural communities, urban neighborhoods, and suburbs, primarily in western Sicily. This organization began to coalesce after 1860 when the newly unified Italian state advanced capitalist development. The commoditization of land was especially disruptive, dispossessing peasants of use rights and exacerbating banditry, animal rustling, and the mayhem of regime change. Uprooted men migrated to cities and, after the 1880s, abroad; some joined urban gangs. Amid this turmoil, self-anointed estate guards, rentiers, demobilized soldiers, and fledgling merchants came together in secretive sodalities. Participants presented themselves as vigilantes who, through cultivating a reputation for violence, promised to restore a feudal form of justice. Among other interventions, they shielded landowners and vulnerable enterprises from brigands and gangsters, collecting or extorting a fee (a *beak-full* or *pizzo*) for the service. They imposed on employers the requirement that they hire particular clients. Mediating local conflicts, they arranged the return, for a fee, of stolen goods, rustled livestock, and unpaid debts. By the turn of the 20th century, there were almost 200 *cosche* with memberships ranging from 10 to nearly 50 plus close associates. This entry provides an overview of the Sicilian Mafia, examining its basic structure and relationship with the state as well as its current status.

Basic Structure

The continuity of a *cosca* over time rests in part on kinship, the status of mafioso being passed from father to son, uncle to nephew. Mafiosi also name each other as godfathers to their children. In (biological) families where the father, uncles, cousins, older brothers, and godfathers are mafiosi, it

is almost obligatory for the next generation to consider a criminal career. Kinship, however, is not the sole basis for recruitment nor does genealogical succession guarantee the right kind of talent. Older mafiosi often pass over sons and nephews who seem unsuited, while gathering around them unrelated youth who, as errand boys and show-offs, appear to have the necessary *guts*.

Each cosca elects its own leaders who enforce a set of rules that apply to the Mafia in general (e.g., prohibitions against adultery, kidnapping, and procuring prostitutes). Leaders also negotiate the terms under which it is permissible to commit murder (e.g., state officials were historically off limits) and oversee adherence to *omertà*, the norm that demands silence before official authorities and commitment to a *man of honor* identity: *real* mafiosi possess the courage, valor, and capacity for violence that render them capable of avenging wrongs without resorting to the law. *Omertà* is further reinforced by the funds each cosca skims from proceeds of the pizzo as these funds are often deployed to pay the lawyers and support the wives and children of members who get arrested and may be pressured to talk. Indeed, only since the 1980s have anti-Mafia prosecutors been able to cultivate justice collaborators (ironically called *pentiti* by the press).

Mafia cosche engage in a common set of cultural practices that contribute to fraternal solidarity and facilitate instant recognition between mafiosi who hail from distant places. Key practices include promulgating a common charter myth, assigning members evocative nicknames, and performing initiation rituals. In a typical ritual, the sponsor, surrounded by cosca members, pricks the initiate's finger, rubs the blood on a saint's image, and sets the paper on fire in the initiate's hands, exacting an oath never to betray the Mafia. Having deemed the novice to be loyal and capable of taking the life of another, the cosca then celebrates at a banquet, replete with rounds of toasts. Banquets also mark other occasions (e.g., weddings and negotiated treaties between rival factions). On many of these occasions, mafiosi strategically invite outsiders (e.g., politicians, priests, local business leaders, occasionally police officials). Many banquets are male-exclusive; indeed, the hosts might well prepare the multicourse meal themselves. Male-only banquets are well known for

sporting hilarious, transgressive, even homoerotic entertainment that binds the assembled revelers and encourages them to consider themselves above the rules of everyday society.

Substantial intermarriage among mafia-related households meanwhile bequeaths to mafia wives a dense web of kinship and friendship; these relations support her as she performs her roles, among them raising future mafiosi. Wives also benefit materially from the enterprises of their husbands, to which they sometimes lend their names as a hedge against prosecution. Although mafia wives may experience the demands of *omertà* as a heavy psychological burden, rarely do they rebel.

The Sicilian Mafia and the State

A crucial aspect of the Sicilian Mafia is its relation to the Italian state. Many have argued that the newly formed state of 1860 was weak and dysfunctional in the less developed South, so much so that the emergent mafias of Campania, Calabria, and Sicily filled a vacuum, performing state-like functions. Eventually, the state made its presence felt but not without being thoroughly corrupted by these mafias. A more plausible interpretation, however, builds on the new Italy's ambition to join the league of the 19th-century capitalist imperial powers, its government and industrial leaders welcoming the regional mafias as adjuncts to the project. By menacing violence, these mafias brought a modicum of order to beleaguered landowners, nascent commercial enterprises, and over-subscribed small businesses. They selectively recruited at-risk youth to their secretive sodalities, calming the incidence of banditry and urban crime. They also lent a hand in keeping at bay anti-capitalist social forces, beginning with late 19th-century socialist movements. The Cold War role of the Sicilian Mafia in tethering Italy to the capitalist West is legendary. This does not mean mafia leaders take the state or other institutions (e.g., the Church, local businesses, the medical and legal professions) for granted; to the contrary, they actively work at befriending persons of authority, in part through orchestrating convivial occasions.

In effect, the relationship between the Mafia and the state transcends the self-serving quid pro quo implied by the word *corruption*. The Italian word

intreccio (i.e., tightly braided strands of hair) is more evocative, with the understanding that the state consists of multiple pieces, some more entangled with criminal organizations than others. Historically, the most involved elements were the dominant political parties, especially the Christian Democratic Party that, with mafia-organized electoral support, expanded politically after World War II. National as well as local politicians in turn protected the Mafia, ensuring that aggressive police officers would be transferred; that forensic evidence and incriminating documents would disappear; that criminal trials would be moved to different venues; that convictions, if they occurred, would be overturned or sentences reduced on appeal. Thanks to this protection, the postwar Mafia achieved a significant presence in state-led initiatives for land reform, public works, and construction. Mafiosi intimidated the populations of their respective territories, but, thanks to government largesse, they also delivered resources to those populations.

No place in Sicily exhibited the postwar *intreccio* of Mafia and state more profoundly than the regional capital, Palermo, and its surrounding areas, the latter covered with commercially oriented citrus groves and orchards but giving way to urban sprawl. Mafia bosses, whether of the city or the orchards, busily brokered relationships between public officials and construction entrepreneurs or, acquiring trucks and construction materials, became entrepreneurs themselves. Contractors and subcontractors indebted to mafiosi obligingly employed the latter's clients; mafiosi, in turn, were able to deliver more votes, most notably to local, regional, and national Christian Democrats. The mafiosi in and around Palermo harnessed additional revenue from their control over wholesale markets for fish, meat, and produce and from levying the *pizzo* on businesses in their respective territories. Individual mafiosi also invested in smuggling (e.g., meat from stolen livestock, American cigarettes to evade the Italian tobacco tax, and drugs for the American market).

Palermo and its orchard hinterland turned out to be an ideal place to prepare clandestine shipments of narcotics for crossing the Atlantic. Before the war, smugglers obtained morphine from Northern Italian and German pharmaceutical companies and hid it in crates of citrus, sardines, and other products destined for transport by ship

to designated Sicilian immigrants in the United States. After the war, mafia leaders in Cinisi, a town near the coast just west of Palermo, convinced government planners to build the regional airport nearby; they and their allies used this facility to ship Southeast Asian heroin, refined in Marseilles by Corsican gangsters, to relatives and friends in America. Following the break-up of the *French Connection* in the early 1970s, mafiosi in Sicily, assisted by chemists from Marseilles, established their own refineries, while a new wave of migrants, some of them relatives of a Cinisi leader, created the pizza connection (i.e., America's heroin distribution network anchored by pizza parlors).

In 1963, Sicily saw the first of two mafia wars occasioned by tension over drugs—in this case, a vicious argument over whom to blame for a wayward shipment of heroin. The second war exploded in the early 1980s, pitting interior *cosche*, centered in the rural town of Corleone, against mafiosi in Palermo and surrounding areas. Historically marginal to trafficking, the Corleonesi suspected the Palermo groups, advantaged as they were by their proximity to ports for shipping orchard produce, to the airport, and to traffickers in America, of excluding them from drug deals. Maneuvering to raise investment capital, the Corleone leaders audaciously kidnapped construction impresarios with whom their rivals were allied, pursuing a bandit-like strategy that violated the Mafia's own rules. As prophylaxis against reprisals, they also infiltrated the most powerful Palermo *cosche*, enlisting the support of persons within them. Although the heads of several *cosche* sought to modulate the mounting conflict through a province-wide *Cupola*, or Commission, an unprecedented number of homicides and disappearances ensued: There were over 500 by 1983.

Current Status

The wars marked a turning point in Mafia-state relations as outright bribes and threats overtook the earlier entanglements. Most spectacularly, the Corleonesi overturned the taboo on killing state officials, initiating a series of assassinations that produced *excellent cadavers*: police investigators, high-level politicians, journalists, and magistrates. Especially vulnerable were the Sicilian magistrates who, building on the pizza connection investigation

in the United States, formed a *pool* to reinforce one another as they followed narco-money and prepared indictments. Best known among the martyred magistrates are Giovanni Falcone and Paolo Borsellino. Massacred in 1992, they had been pioneers of another crucial transformation of the Mafia-state relation: *turning* mafiosi into witnesses for the state. Based on *pentito* testimony, and supported by an anti-Mafia social movement, they and succeeding prosecutors won convictions against an unprecedented number of mafia leaders.

The depositions of the justice collaborators depict life in the Mafia as highly stressful, the more so in light of the narcotrafficking *wars*. Petty rivalries and provocations are ubiquitous, failures to pay respect are long remembered, and suspicion of potential betrayal or treachery demands preemptive action. Even initiations are a cause of tension, reinforcing, as they do, each novice's fealty to a sponsor, ambitious for his own power base in the organization. Hero worship and patronage, intrinsic to the recruitment process, easily disrupt the solidarity of the brotherhood. Generating intensely affective dyads, they define the axes around which factions develop; disputes over territorial authority and over critical resources are often infused with quests for respect and affection.

Supposedly, a cosca uses its common fund to cushion the livelihoods of rank-and-file *soldiers* when they are in difficulty, but cosca leaders, however charismatic, may or may not be generous. Most adopt a demeanor that communicates authority and latent power; they want their dominion to be acknowledged through the obvious deference of others. Nor do they usually advertise difference, adopting modest dress and eschewing other markers of status. The inevitable exceptions, nurtured especially by profits from drugs, are a constant source of trouble. Hot-headed upstarts, attempting to usurp a leadership position, are not unknown. Paradoxically, although the mafia sodality maintains an ethic of brotherhood among its members, mafioso *brothers* may end up killing one another.

SOCIAL BOND THEORY

Social bond theory asserts that crime is not *caused*, it is simply not controlled. As with other control theories, social bond theories assume that the motivation to commit crime is inherent and natural. In 1969, Travis Hirschi noted that control theory is a theory in which deviation is not problematic; rather, it is a theory whereby scholars seek to answer why people do not commit deviant acts.

Social bond theory is one of the most frequently cited and tested theories in criminology. Although the theory is not without its critics, the influence of social bond theory in explaining deviant behavior cannot be overstated. In the 1960s, using a sample obtained from the Richmond Youth Project consisting of male high school students from the San Francisco Bay area, Travis Hirschi sought to identify the main reasons that they commit delinquent acts. He hypothesized that people who are highly socially integrated should be more likely to possess a stronger bond to society and thus are less likely to risk the negative repercussions that result from following a deviant

pathway. Those who have a weaker bond to society do not risk losing as much and are therefore more prone to a deviance. Hirschi refers to the collective mechanisms of informal social control as social bonds, which comprise four key interrelated elements, discussed in this entry. He predicted that each of these elements, individually and collectively, would influence deviant behavior. The presence of these elements would prevent the individual from being deviant and lead to conforming behavior in a society.

The Elements of the Social Bond

The first element of the social bond, *attachment*, indicates how close someone is to the conventional social world. This element has been very prominent in early control theories and showed an inverse relationship between parents and peers when first tested by Hirschi. An individual who is highly sensitive to the opinion of others has a higher likelihood of displaying attachment. Examples include emotional attachment to peers, parents, friends, and teachers, who will deter individuals from committing criminal behavior due to a fear of losing that respect and emotional attachment of others. Regarding attachment, Hirschi focused on three different types of relationships: parental, school, and peer attachments. His original hypothesis included three different dimensions of attachment to parents: supervision, intimacy of communication with parents, and affectional identification. The results revealed support for attachment; boys who were more attached to their parents were less likely to commit delinquency acts.

Commitment is the second element of the bond. It is the rational element of conformity. It refers to the investment an individual puts toward conventional goals, relationships, or activities. People with future educational or occupational goals will be deterred from criminal activity by the fear of losing the opportunity of achieving those goals. Engaging in criminal behavior produces a risk that can prevent someone from successfully accomplishing goals, establishing meaningful relationships, and participating in constructive activities. For example, being in prison does not allow someone to finish law school or achieve

occupational goals. A potential offender will weigh the conventional commitments against the consequences of offending; if there is a great deal to lose, the offender will perceive the risk not to be worth the payoff.

The third element of the social bond is *belief*. The validity of belief rests on the recognition of social consensus or a shared set of values within a given society. Belief has to do with the internalization of a moral system, the ability to distinguish *right* and *wrong*. The degree to which an individual believes in the moral validity of certain norms, the less likely he or she will be to deviate from them. An individual who does not feel tied to the social norms would be less likely to be bound by them and, therefore, more likely to violate the social norms.

The final element of the social bond is *involvement*. This element is centered on the idea that an increase in the amount of time spent engaging in conventional activities, the less time one has to become involved in deviant behavior. This element really rests on the amount of time availability a person has; being busy with a variety of conventional activities leads to less opportunity and ability to engage in criminal behavior. The simple logic of this element rests on the idea that there are a limited number of hours in the day. Being heavily involved in schoolwork, sports, and a job leaves little time for deviant activity.

It is important to note that these elements of the social bond are interrelated. Research has supported the general proposition underlying the theory that a weakening or severity of any one or combination of elements of the social bond increases the chances for deviant behavior.

In Hirschi's own test, the four elements of the social bond were analyzed using police and school records as well as self-report data from the Richmond Youth Project sample. The sample included 4,077 students from 11 high schools in Richmond, CA, from 1964. Hirschi provided clear measures for the four elements of the social bond. He found strong support for the attachment bond to parents. Youths who perceive their parents are aware of their activities, communicate effectively, and who reported greater affectional identification were less likely to report delinquency. The effects of attachment to school were weaker than other

variables, but all were related to delinquency in the expected direction. Hirschi found that adolescents who were more attached to parents and school were more likely to attach to their peers as well. Furthermore, he concluded that being attached to delinquent peers seemed to reduce the individual's level of delinquency. He concluded that having delinquent friends is dependent on a self-selection process whereby similar delinquent youth come together as friends.

The two aspects of commitment that were more likely to be related to delinquency are commitment to educational and occupational goals. Hirschi found strong support for the idea that those who desire to achieve educational or occupational goals, and those who are working toward their goals, are less likely to be delinquent. Overall, there is a significant amount of support for Hirschi's predications about the relationship between commitment and delinquency. The least influential element of the bond was involvement. Hirschi explained the lack of support for this element of the bond by focusing on the fact that most deviant acts take very little time to actually unravel. Most criminal and delinquent acts are unsophisticated and take little time; some of the youth who had the highest scores on the delinquency scale had only engaged in deviant activity for a few hours in the past year.

The belief hypothesis required Hirschi to test the relationship between a variety of attitudes about delinquency and the legal system. Hirschi concluded that a lack of respect for the legal system in the United States was the result of weak social bonds and that both belief and other elements of social bond increased the likelihood of delinquency. To summarize, Hirschi suggested that the more attached individuals are to other members of a society, the more likely they are to believe, invest, and be involved in conventional lines of activity, therefore less likely to deviate.

Empirical Research

A large number of empirical assessments have examined Hirschi's social bond theory. A majority of the findings are supportive, while others are mixed or negative. Most studies that have set out to test social bond theory look at separate effects

of each element of the social bond, so they can be considered a partial test of the theory rather than a complete test of the theory. This opens up opportunities for exaggerated effects of elements of the social bond. The empirical relationship between attachment to parents and delinquency has been the most frequently tested bond from social bond theory. And this element has received a considerable amount of empirical support.

There is evidence that commitment has a moderate or null effect on delinquency. Commitment is usually measured with items such as grades, values placed on school and education, and educational expectations. As for involvement, most measures of participation in conventional activities seem to be unrelated or weakly related to delinquency in both cross-sectional and longitudinal research. Despite Hirschi's failure to find support for the hypothesis that involvement in conventional activities is negatively associated with delinquency, a few researchers have been able to find support for the hypothesis. In contrast, some studies find no relationship between delinquency and afterschool activities, community activities, hobbies, recreational activities, or schoolwork. Finally, the notion that belief in conventional morality decreases the likelihood of delinquency has gained a moderate amount of support in tests of control theory.

Social bond theory was the most popular version of control theory in the 20th century. It still commands attention, although the newest generation of criminologists seem more interested in the life course or developmental perspective of Robert Sampson and John Laub. But if one is interested in applying a theoretical perspective that has been subject to considerable empirical attention, social bond theory still ranks among the top control theories in the discipline of criminology.

SOCIAL CONTROL THEORY

Social control theory highlights the importance of social bonds and informal social control to help explain the persistence of and desistance from offending over the life span. This entry begins with a brief look at origins of the theory. Then, it provides a conceptual and empirical review of this theory and concludes with a discussion of Robert J. Sampson and John H. Laub's age-graded informal social control theory, a contemporary theory that expands upon the social control theoretical tradition.

Origins

The roots of social control theory trace back to the 1600s and 1800s, in the early works of Enlightenment scholar Thomas Hobbes and the sociologist Émile Durkheim who emphasized the importance of social norms, institutions, and laws for restraining individual impulses and behavior. The ideology behind these theories began to be applied to criminology in the 1950s and 1960s when a number of scholars began focusing on the internal and external sources of informal social control (e.g., personal control, family, school) that restrain individual behavior. The most well known of these, social control theory, was developed by Travis Hirschi in 1969.

Delinquency and Crime

Social control theories of delinquency and crime focus on how social relationships and institutions can influence and control individual behavior. Social control theorists assume that individuals

exercise free will and are inherently oriented toward pursuing self-interest. Based on this assumption of human nature, social control theorists are not interested in the question of why people engage in deviance and crime. Rather, the real question of interest is, why do people conform to norms and laws given this inherent self-interest? For social control theorists, socialization into the collective conscience and conventional social order restrains the deviant impulses and behaviors of the individual. Individuals who are more strongly bonded to conventional society, institutions, and others are more likely to obey the law. More recently, social control theorists have highlighted the quality of adulthood bonds to conventional social others, such as involvement in a high-quality marriage, arguing that cumulative involvement in such relationships can facilitate desistance from criminal offending among chronic offenders.

The most notable early control theory of delinquency was put forth in Hirschi's *Causes of Delinquency*, which has been credited as the first comprehensive articulation and empirical test of social control theory. According to Hirschi, adolescents that are strongly bonded to conventional society and social groups, such as family and the school, are more likely to obey the law. The social bond consists of four dimensions and reflects an adolescent's attachment, commitment, involvement, and belief in conventional social institutions, such as the family and school.

Attachment

The first dimension of the social bond is attachment to conventional society and is conceptualized as the emotional aspect of the social bond. Hirschi focused on conventional social relationships that are salient in adolescence, such as family and school. He found that adolescents who are highly attached to, or have warm feelings toward, their parents are less likely to engage in delinquency because they care about the opinions and approval of their parents. Hirschi suggested, then, that high emotional attachment to parents and family acts as virtual parental supervision, as the parent need not be present to exercise control over the child's behavior. Studies reveal that

adolescents who report stronger attachment to their parents are less likely to self-report delinquency. Similarly, research also indicates that adolescents who report stronger parental supervision, and communication and support from parents or caretakers report lower self-reported delinquency.

In addition to family bonds, Hirschi hypothesized that attachment to school (i.e., a general like or affection for school and communication or support between student and teacher) is related to lower self-reported delinquency. Although some studies have found that adolescents who report stronger attachment to school are less likely to engage in delinquency, other studies have questioned the causal nature of this relationship. For example, involvement in delinquency can disrupt and erode social bonds to school by increasing the probability of truancy and poor school performance, both of which are also related to increased involvement in delinquency.

Finally, although Hirschi did not focus on the effects of attachment to delinquent peers on adolescent delinquency, several subsequent studies have found that association and attachment to delinquent peers is a strong predictor of adolescent delinquency.

Commitment

The second element of the social bond, commitment to conventional society, refers to the extent in which adolescents rationally assess risks and rewards of conventional activities and view the importance of conventional, age-appropriate activities. Hirschi's original measure included the extent to which respondents view education as important and their self-reported involvement in adultlike activities (e.g., smoking, dating). Adolescents highly committed to age-appropriate conventional activities are generally less likely to engage in delinquency.

There is strong support for the effects of commitment on self-reported delinquency. Several studies have found that adolescents who are highly committed to educational aspirations are significantly less likely to report delinquency, whereas those committed to adult activities were more likely to self-report delinquency. Finally,

subsequent studies have also indicated that commitment to academic performance (grade point average) is a moderately strong predictor of school misconduct, drug and alcohol use, and delinquency. Adolescents who are more committed to academic achievement and performance, then, are less likely to engage in problem behavior.

Involvement

The third element of the social bond reflects involvement in conventional activities such as school, religious education, employment, homework, and talking or hanging out with friends. Hirschi believed the more involved adolescents are in conventional activities, the less likely they are to engage in delinquency. However, Hirschi's results indicated the weakest support for involvement and delinquency. Contrary to expectations, leisure activities such as talking with friends, riding in a car, and frequenting drive-in restaurants were all associated with higher reports of delinquency. Time spent on homework, however, was related to lower levels of self-reported delinquency.

Recent evidence suggests effects vary according to the type of activity and, in particular, the structured and supervised nature of the activity. In other words, there is stronger support for involvement in academic or school-based activities for reducing delinquency, as compared to involvement in other activities (e.g., dating, riding in a car, talking with friends). Thus, it is involvement in highly structured, supervised activities that is related more consistently to lower levels of delinquent behavior.

Belief

Finally, the fourth element of the social bond refers to a belief in the moral order of society or legitimacy of the law. Those adolescents who have internalized the collective morality, as measured by self-reported attitudes, are more strongly bonded to conventional society and therefore more likely to obey the law. Additionally, self-reported belief was positively correlated with other elements of the social bond, such as attachment and commitment.

Age-Graded Informal Social Control Theory

Hirschi's original social control theory was developed and tested on adolescents and thus focused on the social bonds most salient for explaining adolescent delinquency. Sampson and Laub subsequently extended social control theory by arguing that social bonds are not only salient for the explanation of adolescent delinquency but also for explaining persistence of and desistance from criminal offending in adulthood. Specifically, in a series of influential studies put forth in the 1990s and 2000s, they introduced an age-graded theory of informal social control that argues that social bonds to conventional institutions change over the course of the life span, and such changes in adolescent and adulthood social bonds can explain both persistence and desistance from criminal offending over time. Age-graded informal social control theory asserts that an individual's relationships with conventional others and social institutions (e.g., family, school, marriage) change over the course of age and, as a result, can both strength and weaken one's bond with conventional society. The three main articulated propositions of age-graded informal social control theory address: (1) the relationships between structural context (e.g., family structure), informal social bonds (e.g., attachment to parents), and adolescent delinquency; (2) explanations of continuity (persistence); and (3) change (desistance) in antisocial and criminal behavior between childhood and adulthood.

Structural Context, Informal Social Control, and Adolescent Delinquency

In line with traditional social control theory, Sampson and Laub argue that low parental supervision and weak parental attachment directly increase adolescent delinquency. They also argue that structural factors such as family disruption and socioeconomic status can impact informal social control thereby influencing delinquency. For example, socioeconomic disadvantage and household overcrowding can weaken parental supervision and disrupt attachment to family and school, which in turn, increases the probability of adolescent delinquency.

Continuity in Childhood and Adulthood Antisocial Behavior

An enormous amount of literature indicates considerable continuity in antisocial behavior from childhood to adulthood. Prior behavior, then, is one of the strongest predictors of future behavior. Sampson and Laub acknowledge that early individual predispositions (propensity) to antisocial behavior may indeed lead to stability in behavior from childhood to adulthood but also argue that repeated negative experiences with formal institutions of control can also contribute to stability in antisocial behavior. For example, repeated involvement with the juvenile justice system in adolescence can lead to negative consequences (e.g., arrest, detention, school suspension) that erode bonds to conventional society and cut off future opportunities for conventional behavior (e.g., employment) in adulthood, reflecting a process they term *cumulative continuity* or disadvantage. Thus, delinquency in adolescence can weaken informal social bonds to conventional institutions during adolescence, leading to continuity in antisocial behavior in adulthood.

Numerous studies across time and place have demonstrated that early childhood antisocial behavior is a strong predictor of future, adulthood criminal behavior. Additionally, studies have confirmed that stability in antisocial behavior over the lifespan is a result of both individual propensities and cumulative continuity.

Changes in Childhood and Adulthood Antisocial Behavior

Sampson and Laub argue that in spite of stability in antisocial behavior between childhood and adulthood, involvement in conventional social relationships later in life can strengthen one's bond to society and can lead to desistance from criminal offending in adulthood. In their seminal study examining criminal offending among men from the approximate ages of 14 until their 70s, Sampson and Laub demonstrate that strong marital attachment and involvement in stable employment can act as turning points in the lives of adult offenders and lead to significant reductions in reoffending. Additional studies also confirm the importance of these institutions for reducing both short- and long-term criminal offending patterns.

The evidence for age-graded informal social control theory has generally been supportive. Social relationships and bonds to conventional others and institutions can influence criminal offending, both in adolescence and adulthood. Whereas Hirschi's original control theory focused on the social relationships and social bonds that are relevant for adolescent delinquency, Sampson and Laub extend social control theory to also focus on adulthood social relationships and social bonds. As a result, age-graded informal social control is able to explain onset, persistence, and desistance from criminal offending over a lifespan. Although Hirschi's original social control theory has been less studied over time, social control theory lives on in contemporary developmental theories such as age-graded informal social control theory.

SOCIAL DISORGANIZATION THEORY

In general, social disorganization theory maintains that the cause of delinquency (i.e., crime) is associated with locations rather than individuals. This theory is based on research findings that suggest delinquency occurs in the same areas as social problems like unemployment and poverty. This makes social disorganization theory a macro-level theory because the units of analysis are neighborhoods and communities, not offenders. Social disorganization theory is a mix of control theory and learning theory. Many of the controls evaluated by social disorganization theory are informal controls. When a neighborhood or community is unable to maintain social controls (i.e., agreed-upon values and norms), the result is an atmosphere in which crime more easily occurs. This entry examines the history of social disorganization theory, the relationship between neighborhood characteristics and crime, the introduction of collective efficacy to the theory, and the challenges associated with measuring social disorganization.

History

Social disorganization theory is rooted in the work of Robert Park and Ernest Burgess, who were human ecologists (i.e., researchers who seek to understand social processes). Park and Burgess began their work in Chicago in the 1920s where many social changes were occurring due to an influx of foreign-born immigrants. As the city expanded, many areas began to experience a change in land use. This expansion changed the layout of Chicago not only by expanding the city but also actually creating large areas of transition between the city center and the suburbs. Just as in

natural ecology, Park and Burgess observed invasion, dominance, and succession when examining the social processes of Chicago. Examples of this would include different areas being rezoned from commerce to residential. Additionally, there are examples of neighborhoods changing from racially homogenous to heterogamous. Park and Burgess divided the city into concentric rings known as *zones*. Each zone was characterized by a specific type of land use and, in turn, type of occupant.

The city center was labeled as Zone 1 and primarily consisted of stores, businesses, and office buildings. Zone 2 was a zone of transition and was comprised of a mix of factories and deteriorated housing. This zone of transition was so named due to businesses moving in, while those who could afford to moved out. Zone 3 was mostly occupied by single-family tenements and was widely considered to house the working class. Zone 4 was a residential zone that contained mostly single-family homes with yards and was occupied by what tended to be the middle class. Zone 5 was the final and furthest zone from the city center. This zone was commonly referred to as the *commuter zone* and consisted of suburbs populated by upper middle-class families.

Conducting a systematic observation of these zones from the 1940s through 1960s birthed the concentric zone theory that Clifford Shaw and Henry McKay used as a base for social disorganization theory. It is important to note that Park and Burgess did not use this method to study crime; rather, they focused on social processes and interactions.

Relationship Between Neighborhood Characteristics and Crime

Shaw and McKay used this concentric zone theory to examine parallels between delinquency and the social characteristics of a neighborhood. Using official records of juvenile delinquents and census data to create delinquency rates for specific areas in Chicago, Shaw and McKay found that the zones in transition tended to have more crime than those that were stable. They also used interviews to add to their quantitative research, gathering life histories of juvenile delinquents. Up to this point, most of criminological research

focused on the individual causes of crime and delinquency rather than social causes. Through their research, Shaw and McKay were able to make comparisons across different zones, while associating the social characteristics of those zones with the delinquency rates. Their primary findings suggested that delinquency occurs in the same areas as social problems like unemployment and poverty. This led them to the idea of social disorganization, which means there is an inability of the community to realize shared values and therefore an inability to maintain effective social controls. According to the theory, crime will occur without these social controls.

For a neighborhood to have social controls, it must have high solidarity, cohesion, and integration. Solidarity means that a neighborhood must have agreed-upon values and norms. Cohesion refers to residents of a neighborhood having a strong bond with one another (i.e., they know and like one another). Finally, integration means that there are frequently occurring social interactions among residents. Together these elements create a strong, organized community resulting in higher informal controls and less crime because people feel comfortable, and even obligated, to watch out for their community. Therefore, socially organized communities will have people who share the goal of living in a crime-free area, know and talk to each other, and frequently interact with each other. Conversely, residents in disorganized neighborhoods will not talk to each other, making it easier for crime to occur. It should be noted that the control is all informal and not official. Some argue that the formation of gangs occurs when juveniles seek to form their own social controls. It is in this idea that the social learning aspect of the theory comes into play. That being said, this aspect of social learning is not frequently associated with the main concept of the theory.

To examine social disorganization in a neighborhood, typically, measures of racial heterogeneity, residential mobility, and income-based estimates of socioeconomic status are used. It is believed that neighborhoods with high racial heterogeneity will be disorganized because the residents will never be able to achieve a consensus due to the fact that they have different goals. Furthermore, racial heterogeneity impedes communication: Residents do not

talk to one another about suspicious activity in the neighborhood. High residential mobility results in unstable communities (i.e., residents tend to avoid getting to know one another). With a lack of residential interactions comes a lack of social informal controls. It is thought that lower socioeconomic status areas lead to higher racial heterogeneity, residential mobility, and more disorganization. It is important to note that social disorganization theory does not refer to disorganized residents but only to a disorganized community. Additionally, it should be noted that these elements themselves do not directly cause crime nor does a disorganized community. These elements only serve to mediate the occurrence of crimes in an area.

Remaking Disorganization Theory: Collective Efficacy

Social disorganization theory began to be viewed as irrelevant because of the idea that the theory itself was a manifestation of middle-class bias toward inner-city lower-class neighborhoods. Many argued that there were no actual measures of the amount of social disorganization within a community. Robert Sampson and Byron Groves revitalized the theory using 1984 data from Britain by including family disruption and urbanization as some of the causes of social disorganization. Sampson and Groves, using self-reported juvenile data from both the United States and the United Kingdom, found support for social disorganization when using additional measures like social networks and participation in formal organizations. This was a more in-depth study of social disorganization because it included mediating effects rather than just exogenous variables and outcome measures. Their study found that communities with greater informal controls and social ties had lower rates of delinquency. Additionally, they found higher control of teenage peer groups that have lower rates of property crimes. The inclusion of these new variables changed the scope of social disorganization. It was then that collective efficacy became a relabeling of social disorganization theory, thereby increasing its popularity once more.

Collective efficacy refers to the extent to which neighborhood residents can marshal their own informal social controls, making the variable an

alternative to social disorganization. An example of this would be a neighborhood where there is high collective efficacy, or adequate social controls, having a low crime rate, whereas in neighborhoods with low collective efficacy, the crime rate will be high. Having better measures of the mediating variables allows for communities that have low socioeconomic status and high racial heterogeneity, yet still have a low crime rate due to high collective efficacy. Social disorganization theory uses delinquency rates to explain social disorganization; however, the theory states that delinquency is caused by social disorganization, making this theory tautological. Collective efficacy, on the other hand, focuses more on how certain aspects of a neighborhood cause social disorganization and in turn victimization and offending. Much of the research in this area examines juvenile delinquency. It is thought that having high collective efficacy has actually had a protective effect on children due to increased social controls.

Challenges Associated With Measurement

One of the biggest problems when examining social disorganization theory has been determining the proper way to measure social disorganization. As mentioned previously, socioeconomic, racial heterogeneity, racial mobility, family disruption, and urbanization are all factors that have been examined in studies of the theory. It has been argued that social disorganization is too abstract to truly be measured and that aforementioned variables do not truly measure social disorganization. This argument primarily points to the inability of these variables to measure informal social controls. According to this line of thinking, only secondary variables are being considered. For example, measuring residential mobility does not provide the actual amount of social disorganization within a community. Rather it measures something that could lead to social disorganization. Many researchers have sought to use survey data and interviews as a means of filling this gap. Such research asks questions about how individuals would react if their neighbors were being victimized. It is believed that the collective answers within a community are an accurate measure of collective efficacy. Another major critique of the

theory is that using official data for crime counts produces biased results since many argue that the juvenile criminal justice system was particularly biased during the 1920s and 1930s, when the early data used to fuel the theory were collected.

Final Thoughts

The findings of theorists like Park and Burgess, who used concentric zones to examine social ecology, laid the framework for Shaw and McKay. Park and Burgess placed Chicago's business district at the center of their map and made the neighborhoods surrounding it Zone 1. This zone contained the highest concentration of delinquents as well as the greatest poverty. Building on the work of Park and Burgess, Shaw and McKay discovered a strong relationship between neighborhood characteristics and delinquency. Additionally, the neighborhoods suffering from high crime rates had physical deterioration, a higher percentage of foreign-born individuals, more residential mobility, and other assorted social ills such as unemployment and disease. According to Shaw and McKay, neighborhoods existing in such conditions have higher levels of social disorganization and weak social controls, thereby causing crime. Many of these types of neighborhoods are found in inner-city locations; therefore, virtually all of the research on social disorganization theory is conducted within urban areas. Such findings led to the conclusion that social disorganization causes delinquency. It was Sampson and Groves who expanded on this theory by adding additional variables (e.g., family disruption and urbanization). With the inclusion of these measures, collective efficacy reinvigorated the idea that informal social controls mediate crime in certain areas.

SOCIAL DRIFT THEORY

Social drift is the gradual process of changing status relative to others. This often pejorative concept applies to individuals as well as groups and is used in criminology, psychology, sociology, and other disciplines. People are said to drift into criminal enterprise, drug addiction, poverty, alienation from society, or homelessness, for example. Social mobility (i.e., the ability to move within a stratified status structure in a society) influences social drift. If upward mobility is blocked or perceived to be, downward drift is more likely. This essay describes social drift theory, provides an overview of the history of criminology, and examines the relationship between drift in socioeconomic status (SES) and criminal behavior.

Defining Social Drift

Social drift refers to behavioral observations, such as drifting into delinquency, and the theoretical basis for these observations, such as psychopathy or antisocial personality (labeled conduct disorder and antisocial personality disorder in *The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*). There are intergenerational (e.g., children compared to parents) as well as intragenerational (i.e., changes during the person's life), measures of drift, and relevant terms include *upward*, *downward*, and *horizontal* (i.e., change that is not directional) drift. In criminology, social drift is part of a more inclusive framework called *social control* or *social bond theory* that highlights the breakdown of internal (conscience) and external (societal) controls on deviant behavior.

History of Criminology

Religious and demonic themes pervaded ancient thinking on criminal behavior, while during the Middle Ages in Europe, ideas such as opportunity and low self-restraint, believed to culminate in an individual's decision that potential advantages of crime outweighed possible costs, became popular. This reasoning led to the development of the classical school of criminology in the 18th century and a focus on the laws and consequences of transgressions. Since individuals could freely choose to break a law (i.e., they had free will), they earned the punishment that fits that specific infraction. Although influential (e.g., the Eighth Amendment to the U.S. Constitution, the *Three Strikes* statute of the Violent Crime and Control Law Enforcement Act of 1994), this classic view generally has been replaced by variations on the positivist perspective.

Classicists emphasized the role of free will, or choice, in criminology and focused on the infractions. An inherent problem is that *will* is a hypothetical construct deduced by observing behavior, an example of circular reasoning, and does not explain why some people behave illegally, while others in similar situations do not. It is a meta-physical or abstract label, or to use psychological language, a latent trait that is posited as the predominant attribution (i.e., cause). Furthermore, since people can exercise their free will to transgress or not, the punishment is designed to fit the crime, and consequences are determined according to black-letter law, the *law on the books* such as the influential Model Penal Code written in the 1960s by the American Law Institute.

In the 19th century, positive criminology (positivist school, positivism) shifted the focus from the law to the person (i.e., punishment fit the criminal and context); criminals are born (nature) not made (nurture). Second, positivism sought a scientific, empirical basis. Third, it incorporated combinations of biological, psychological, and sociocultural determinants. Positivists investigated differences between criminals and conventional people, through their character (e.g., Robert Hare's psychopathy), physiology (e.g., Cesare Lombroso's criminals' facial features), or interactions with others (e.g., Edwin H. Sutherland's differential associations). This spotlight on

antecedent conditions continues in criminological theory and research.

SES (i.e., one's relative position in a hierarchical class-based social system) is associated with physical and mental health and criminal behavior in predictable ways. There is a documented SES–health gradient effect (i.e., positive correlation) between higher SES and better health and an inverse relationship (i.e., negative correlation) between nonwhite-collar crime and SES. Two proposed theories explain these associations, namely, social selection (i.e., drift) and social causation (i.e., environment). A third approach, reciprocal causation, combines the two. Analogous to nature–nurture, selection–causation has relative, not absolute, influences on outcomes; and to extend this simplistic analogy, illness–criminality (i.e., nature) selects toward downward drift in SES, while low SES (i.e., nurture) causes illness–criminality.

Relationship Between Drift in SES and Criminal Behavior

A fundamental question is whether psychopathology and/or criminal behavior causes downward drift in SES, or low SES environments (e.g., stress, poverty) cause the manifestation and identification of psychopathology and/or criminal behavior. The direction of causation remains empirically unresolved, and research results are mixed, suggesting that both causation and selection mechanisms are involved. Although unresolved, this remains an important practical issue as government budgets tighten, the focus shifts to prevention and early intervention, and accountability for resource allocation becomes paramount. For example, should governments invest more in building prisons, reducing poverty rates, mental health research and treatment, or education?

Psychopathology and criminality are interrelated and embedded in social contexts. Persons with mental illness have higher arrest rates. Criminalization theory states that societies determine what behavior is considered illegal, threatening, or disturbing, then label and stigmatize it accordingly through laws and psychopathology classification systems (e.g., *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*), and social structures influence the probability and

outcomes of encounters with the justice system. For example, those deemed *homeless* have less access to legal lodgings and mental health care, are more likely to attract unwanted attention from police officers, and have higher rates of diagnosable mental illness compared to people without this societal label. Similarly, persons diagnosed with certain *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* diagnoses, such as antisocial personality disorder and substance use disorders, have higher arrest and incarceration rates, and both reflect societal values. People who use illegal drugs are subject to arrest more often than treatment. Labeling stigma, criminal records, mental health treatment histories, and societal rejection can add pressure toward downward drift. In addition, individuals with higher social rank are less likely to be labeled with a diagnosis, arrested, or hospitalized. Proponents of the criminality perspective, on the other hand, explain this correlation simply by pointing to differences in crime rates between these groups and observe that people with mental disorders commit more crimes.

In 1964, David Matza published his classic book on juvenile boys' social drift into delinquency, *Delinquency and Drift*. He countered the reigning theory in criminology, positivism, and its predecessor, classical criminology, with his own explanation that combined aspects of each. Matza's theory focused on the causes of delinquent drift after social controls, or constraints, were *neutralized* such that the individual no longer felt bound by law. The concept of drift assumes a potential for delinquent behavior. Only those who have this potential are at risk, and only those who have the requisite criminal skill levels (i.e., learned behavior), which are low in common types of delinquency (e.g., shoplifting, burglary, illicit drug use and distribution), plus low apprehensiveness are at risk.

Matza posited preparation and desperation as the salient influences on drift. *Preparation* includes learned skills, low fear, and prior success committing infractions. This leads to repeat offending. Fear level reduces through beliefs in the low likelihood of arrest, the incompetence of those in authority, and the inconsequential and incremental nature of postarrest consequences for children.

Desperation involves what psychologists now call *learned helplessness* (i.e., the belief learned

from experience that one has no control over what happens to oneself). In the delinquent subcultural group with its sense of community, this is experienced as a reduction in manliness that can be restored through criminal conduct, especially more audacious or new types of crimes that elevate in-group status.

Edward Jarvis conducted a seminal epidemiological study in 1855 that assessed the prevalence of psychiatric disorders in Massachusetts and found strikingly higher rates in the *pauper* compared to the *independent* classes. This essential finding holds true today. Social selection (i.e., existing pathology causes lower class standing) was posited as the cause. This fits with moral causality theory and pseudoscientific, quasi-biological beliefs such as phrenology and eugenics, which were popular at that time, and the practical reality of few effective treatments for mental illness. This perspective downplays the role of social environment in favor of genetic or other biological factors in the development and maintenance of psychopathology and resultant disparities in social class. However, while advances in biological psychiatry and classification trends reflected in later editions of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorder* provide more evidence of the importance of biology in the etiology (i.e., causes) of mental illness, environmental influences cannot be ruled out.

Geographic, occupational, and financial social drift have been investigated as explanations for observed SES–mental health disparities. This perspective predicts that those with serious mental illnesses, particularly if they involve hospitalization, would tend to move to less costly communities as well as experience declining employment and more financial insecurity compared to others. Although the idea that poor health triggers downward drift is intuitively appealing (i.e., has face validity), there is little intragenerational or intergenerational research support for the social selection–drift hypothesis, except for children with early onset psychotic disorders (e.g., schizophrenia) or serious childhood disruptive behavior (e.g., aggressiveness, hyperactivity, and poor social adjustment).

In addition, the life cycle can be examined to assess the cumulative effect of SES disadvantage on health and criminality and effects on social drift. Developmental and life course criminologists assert

that early onset starts a path toward criminality and away from conventional lifestyles. Early offenders have more conflict at home and school and with peers, which starts an escalating criminal drift process. Analogously, a chronically ill or delinquent child can cause a downward trajectory in social and economic viability for middle-class families, both in terms of lost income and future prospects and in terms of social isolation and decreased self-esteem. On the other hand, there is evidence that some marginalized families benefited from learning care-taking skills and successfully managing the challenges, which improved self-esteem and increased social connection.

Whether early or late initiation of criminal activity is more criminogenic and why remains equivocal. The Cambridge Study in Delinquent Development, launched in 1961, was a longitudinal study of predominantly White working-class 8- to 9-year-old boys in London. Results indicated those who committed first offences at earlier, younger, ages reoffended more often and for a longer period of time compared to later onset offenders, reflecting a greater propensity for criminal behavior. This example of propensity theory supports social drift theory. However, other studies suggest late onset as more predictive of reoffending, and propensity theorists generally discount onset age as causally significant. They focus on the tendency (i.e., propensity) toward antisocial action that is in the individual exacerbated by family (e.g., poor parenting, parents' criminal history) and social (e.g., poverty, education) factors.

Final Thoughts

A century of data disputes the poverty-causes-crime thesis. Crime rates plummeted during the Great Recession of the 1930s, increased during the expanding economy of the 1960s, and dropped after the 2008–2009 recession. The 21st century witnessed a return to strict social control of crime through policies such as data-driven policing strategies, mandatory sentencing, and privatizing prisons (i.e., prison–industrial complex).

Areas of interest in criminal psychology now include the relevance of improving the quality of social connections for those at risk and strengthening the explanatory power of theories in criminology, psychopathology, and criminal psychology. Social connections appear to be

crucial in explaining, for example, the shorter time between diagnosis and mental health recovery in some developing countries compared to the United States and Europe and designing prison to community transition programs.

The merit of criminal psychology is its accuracy and ability to predict future behavior. The challenge remains to establish an objective, empirical, replicable scientific basis that can be applied to solve practical problems. Social drift theory contributes to this scientific basis, and further research will determine its specific contributions and relevance.

SOCIAL LEARNING AND ENVIRONMENTAL DETERMINANTS OF PSYCHOPATHY

The construct of psychopathy is most frequently characterized as a lifelong, persistent condition associated with a lack of capacity for empathy, interpersonal/affective deficits, and engagement in social deviance/antisocial behaviors (e.g., aggression). There are several different environmental influences that can impact psychopathy. These include, but not limited to, childhood abuse and/or trauma, caregiver/parental bonding and resultant insecure attachment styles, and community and/or peer influences. Understanding factors that contribute to the development of psychopathy is of paramount importance to criminal justice and

forensic psychology professionals due to its impact on criminal offending, forensic assessment, treatment amenability, and recidivism.

Environmental experiences may interact with biological factors in a process known as *biological embedding*. Clyde Hertzman and Tom Boyce (2010) define *biological embedding* as follows, “biological embedding occurs when experience gets under the skin and alters human biological processes; systematic differences in experience in a socially partitioned environment lead to different bio-developmental states; the differences are stable and long-term; and these differences influence health, well-being, learning, and/or behavior over the life course” (p. 330). All of these factors play a role in *epigenetics*, which is defined by Andrea Gonzalez (2013) as “the altering of a gene’s function without altering the gene’s structure or sequence” (p. 417). Psychopathy is influenced by both biological and environmental factors.

Andrea Glenn and Adrian Raine discuss important factors to consider regarding the debate as to whether psychopathy is causally influenced more so by genetic or environmental factors. Glenn and Raine discuss how people often misinterpret the fact that although scientific research may report findings suggesting brain abnormalities and/or deficits in individuals with psychopathic characteristics, those findings do not necessarily mean that psychopathy is a condition that only has a biological basis. They continue their explanation of the aforementioned discussion by stating, “in reality, the brain is just the machine that the biological and environmental factors act upon. The factors that make our brains function the way they do can be either genetic or environmental in origin, or more likely a combination of the two” (2014, p. 14). This entry discusses the process of biological embedding and the environmental determinants of psychopathy as they relate to psychopathy.

Biological Versus Environmental Determinants

A core component of psychopathy is emotional disturbance, which may be caused by environmental factors impacting the emotional and moral development of an individual. Environmental

influences, such as childhood abuse or trauma, insecure attachment styles resulting from poor parenting, and adverse community or peer influences, may impact the development of psychopathic traits.

Environmental influences are contributing factors of psychopathy in and of themselves; however, when they also interact with biological components of psychopathy, the result may be a more pronounced form of psychopathy. Glenn and Raine posit that any changes in the severity of psychopathic traits across time are a result of environmental determinants. Lisa Marshall and David Cooke contend that adverse familial experiences in childhood are commonly associated with low- to moderate-level psychopathy. Somewhat surprisingly, however, the majority of individuals classified as severe psychopaths come from good homes. According to Marshall and Cooke’s 1999 study, the contention is that the familial factors or variables contributing to what is considered a *good home* includes competent parenting comprised of appropriate parental discipline and supervision as well as lack of parental discord, antipathy, and abuse or neglect. This suggests that perhaps psychopaths at the extreme end of the severity spectrum may have more of a biological predisposition to psychopathy when compared to those at moderate levels or the low end of the psychopathic continuum.

Childhood Abuse or Trauma

High rates of childhood victimization are associated with increased scores on the Psychopathy Checklist–Revised and an increased likelihood of violent or antisocial behavior. Common symptoms of trauma include anxiety and fearlessness. Anxiety can be associated with the affective component of psychopathy, while fearlessness can be associated with the antisocial facet of psychopathy. Childhood abuse or trauma can be physical, emotional, sexual, or neglectful in nature.

Each type of trauma can impact the developmental trajectory of psychopathy overall as well as specific facets of psychopathy. For instance, childhood sexual abuse can be associated with the grandiose and manipulative interpersonal style of psychopathy, the impulsive aspects of psychopathy,

and the antisocial behaviors associated with psychopathy. Childhood neglect is associated with the flattened affect and antisocial behavior components of psychopathy. Childhood physical abuse has only been tentatively associated with the antisocial behavior aspect. It has been posited that many psychopathic individuals experience complex trauma, which is the experience of different types of abuses and violence, such as an individual experiencing both sexual and physical abuse.

These early traumatic experiences may impact different brain structures. The ventromedial prefrontal cortex is essential in several areas in which psychopaths commonly exhibit deficiency. These include impulse control, socioemotional responses, interpersonal abilities, and empathy. Decreased ability and/or lack of impulse control results in an increased likelihood of engaging in antisocial and impulsive behaviors. The amygdala, which controls an individual's fear response and emotions, may also be impacted by early adversity.

Sex differences may also play a role in the exhibition of psychopathic characteristics. For instance, psychopathic female offenders with histories of abuse tend to score higher on the personal gain and parasitic orientation items of the Psychopathy Checklist-Revised. Male psychopathic offenders have been found to score higher on the interpersonal and antisocial items, especially with regard to poor anger control, irresponsibility, and serious criminal behavior. Overall, childhood abuse and trauma can significantly impact the developmental trajectory of psychopathy.

Parental Bonding and Attachment Styles

Prior research suggests that individuals who display psychopathic traits often experience parental rejection and dysfunctional affectionate relationships early in life. Poor parental bonding, which involves a lack of caregiver care and/or overprotection, is highly associated with psychopathy. This especially occurs when children are separated from their parents within the first 3 years of life, a critical developmental period for children, especially in the development of mirror neurons that foster empathic capacity. The mirror neuron system can only develop appropriately when a caregiver properly models empathy for the young

child. In doing so, he or she assists the child in training their mirror neuron system, which usually engenders secure attachment.

Children who experience early adversity like abuse typically do not develop effective mirror neuron systems, are insecurely attached, and have higher scores on the Psychopathy Checklist-Revised: Youth Version, especially on Facet 4: antisocial behaviors. Harsh or erratic parenting styles can also impact psychopathy scores. Dysfunctional parental relationships can impact behavioral regulations, resulting in antisocial and impulsive behavior.

Dysfunctional or insecure attachment styles can be the impetus for the behavioral, psychological, and antisocial behaviors displayed by psychopaths. Insecure attachment styles may also impact the emotional detachment facet of psychopathy. If this emotionally detached affective style is consistently reinforced, it can lead to the development of callous-unemotional traits, which are common in psychopathic individuals. Insecure attachment styles may also be a result of constant relocation from caregiver to caregiver (as is unfortunately often the case in foster care), which can impact an individual's ability to develop strong attachments.

Dysfunctional relationships with mothers tend to be the most common dysfunctional relationship among psychopathic individuals. Insecure attachment styles can also impact aggression, hostility, and delinquency. The inability to form emotional relationships early in life may cause psychopathic individuals to be unable to form emotional attachments to other people at all.

Severe neglect (and the resulting inability to form strong emotional attachments) is thought to be one of the most important environmental determinants of psychopathy. Not only does it lead to the negative affect component of psychopathy, but it may also lead to the superficial charm or sociability aspect as well. The importance of the role of attachment styles in psychopathy is highly emphasized in the etiology of psychopathy.

Community or Peer Influences

Community or peer influences are highly influential when a model (typically an adult, though can be a peer) is valued by the individual. Influences

from models can come from both inside and outside of the home. An example of influences from inside the home that may incite psychopathic characteristics, traits, and/or behaviors is parental criminal activity. This influence can be especially impactful as it may be present in an individual's formative years.

Community influences are also associated with psychopathic traits. Living in violent areas, which is especially common in low socioeconomic neighborhoods, can increase aggression and antisocial behaviors. Those who live in communities where exposure to violence is prominent may also display an increased amount of psychopathic traits and/or behaviors.

Peers, especially during adolescence, influence an individual's likelihood of engagement in antisocial behaviors and delinquency. Social learning is prominent during these years. Gang membership enhances engagement in these activities as well as in some criminal activities. Psychopaths tend to have low arousal levels. This causes them to be prone to boredom and thrill seeking. This need for excitement may lead them to join gangs and engage in high-risk behaviors, which are usually criminal and antisocial in nature. In fact, individuals with psychopathic traits display extremely high levels of aggression and antisocial behaviors, which are often diagnosed as conduct disorders in childhood and adolescence.

Social Learning and Biological Embedding

Albert Bandura's social learning theory is a reciprocal interaction between behavioral, cognitive, and environmental factors. Social learning deficits are prominent in psychopathic individuals. For instance, the ability to care about how another person is feeling or to feel another's pain (a key component of empathy) is typically acquired through social learning. Psychopaths lack this ability. This may be due in part to the difficulty and/or inability that psychopaths experience as children in forming strong attachments with their parents. The abuse or neglectful relationships that some psychopaths experience at a young age often distort the schemas that they hold about the world.

Psychopaths tend to demonstrate the hostile attribution bias, which, in turn, adversely impacts the relationships that they are able to form with their peers and caregivers. The *hostile attribution bias* is the tendency for an individual to interpret others'

actions as aggressive, even when the actions are ambiguous. Psychopaths also tend to have immature defense mechanisms, deficits in the ventromedial prefrontal cortex, and hypersensitivity to rejection, which can also impact social learning abilities.

The process of biological embedding can occur in many, if not all, of the environmental determinants of psychopathy. Biological embedding is a process by which environmental situations alter biological functioning. In essence, environmental situations or experiences contribute to genetic predispositions, leading to a greater likelihood of psychopathy.

Environmental experiences, such as childhood abuse and/or trauma, can impact biological functioning. For instance, Avshalom Caspi and colleagues report that the enzyme monoamine oxidase plays a role in the gene-environment interaction in childhood, specifically when childhood abuse or maltreatment is present. This effect occurs as both an interaction and as a main effect itself. Biological embedding and epigenetics in tandem with environmental influences and biological predispositions are instrumental in the manifestation of psychopathy and are salient factors of upmost importance to comprehend and consider in the study of psychopathy.

SOCIAL LEARNING THEORY AND COGNITIVE BEHAVIORAL THERAPY

See Cognitive Behavioral Therapy and Social Learning Theory

SOCIAL LEARNING THEORY OF CRIME

Social learning theory of crime refers to a theoretical perspective of crime and criminal behavior, which blends ideas from psychological behaviorism with sociological traditions. In its contemporary form, the theory is associated with sociological criminologist Ronald Akers. His version identifies distinct learning mechanisms crucial to the explanation of both conformity and forms of nonconformity. A recent definition of the perspective offered by Akers and Gary F. Jensen (2006) defines social learning theory as

a general theory that offers an explanation of the acquisition, maintenance, and change in criminal and deviant behavior that embraces social, non-social, and cultural factors operating both to motivate and control criminal behavior and both to promote and undermine conformity. The basic proposition is that the same learning process in a context of social structure, interaction, and situation, produces both conforming and deviant behavior.” (p. 38)

After describing the history and ideas incorporated into social learning theory, this entry reviews the mechanisms of social learning as well as research on social learning theory. This entry concludes with a discussion of the expansion of social learning theory into social structure/social learning (SSSL) theory and possible new directions.

History and Foundational Ideas

Early History

Some of the basic ideas behind social learning theory were expressed by Neal E. Miller and John Dollard in their 1941 book *Social Learning and Imitation*. In the preface, they proposed to “apply training in two different fields—psychology and social science—to the solution of social problems.” Another psychologist, Albert Bandura, extended the study of modeling and vicarious learning mechanisms to adolescent aggression in 1959 and published *Aggression: A Social Learning Approach* in 1973.

Many of the sociological ideas ultimately incorporated into social learning theory emerged at the University of Chicago in the 1920s and 1930s. The basic thesis among these sociologists was that criminal behavior can be explained in the same manner as other forms of behavior and that support for such a view could be found in both ecological patterns of crime and delinquency and in case studies of individuals and groups. In his research on gangs more than 80 years ago, Frederick Thrasher identified regularities in the emergence of gangs that still hold true today and are quite consistent with social learning theory.

Differential Association Theory

Known as the father of scientific criminology, Edwin Sutherland was the first scholar to develop a systematized sociological explanation of criminal behavior in his *Principles of Criminology*, first

published in 1924. By 1939, Sutherland had organized a set of propositions emphasizing the role played by *conflicting definitions* of appropriate and inappropriate conduct in a complex society and *differential association* with people communicating conflicting definitions.

In 1947, Sutherland's systematic elaboration of a theory of both crime and criminality in a set of nine fundamental propositions earned him honors as the most influential theoretical criminologist of the 20th century. Applied to delinquency, the central proposition of differential association theory was simply that "a person becomes delinquent because of an excess of definitions favorable to violation of law over definitions unfavorable to violation of law" (p. 7). Definitions were the symbolic messages communicated in everyday interaction with significant others such as parents, peers, and teachers.

Differential Association-Reinforcement Theory

The two traditions, psychological development of a social learning theory of human behavior and sociological development of criminological theories emphasizing normal learning processes, proceeded rather independently until the mid-1960s. Then, Akers teamed with Robert Burgess, a sociologist trained in operant theory, to modify Sutherland's principles using the terminology and principles of modern behaviorism. This differential association-reinforcement theory of criminal behavior became the foundation for a perspective in criminology that Akers in 1973 deemed *social learning theory*. Social learning put the primary emphasis on mechanisms involving exposure to people and peers, cultural variations, social structures, and social institutions. Differential association-reinforcement included both nonsocial and social learning processes.

Social Learning Mechanisms

Akers elaborated four key explanatory concepts or dimensions of social learning theory: differential association, definitions, differential reinforcement, and imitation. The concept of differential association includes interaction with others who engage in certain kinds of behavior or express norms, values, and beliefs supportive or contrary to such behavior. The balance of people and groups encouraging or discouraging criminal behavior provides the major

immediate and intermediate social contexts in which social learning mechanisms operate. The most important of these groups include the so-called primary groups such as family and friends. Differential association also includes exposure to secondary and reference groups as well as mass media, Internet, computer games, and other *virtual groups*.

The concept of culture is central to social learning theory and encompasses values, norms, and beliefs that can facilitate or inhibit criminal behavior. Sutherland's definitions favorable and unfavorable to lawbreaking as a key variable have endured and continue to play that role in social learning theory. Although definitions played the central role in Sutherland's version of differential association theory, such definitions do not capture all ways of learning delinquency. For example, peer pressures to *go along* can increase the odds of delinquency even when a youth defines the activity as wrong. Concern about parental reaction can inhibit delinquency even when a youth does not define the activity as something he or she ought not to do. In short, in contrast to differential association theory, social learning theory stresses nonnormative as well as normative learning mechanisms that can lead to or inhibit delinquency. Social learning theory fits with differential association theory in that the learning processes are normal and can involve learning of expectations that conflict with the law.

The original emphasis in Sutherland's theory was on cultural conflict in society as a whole, with some forms of criminal behavior merely being attempts to abide by enduring subcultural traditions taught and learned through normal socialization in some groups and settings. This conception was the foundation for the conception of Sutherland's theory as a *cultural deviance* theory. Variations in crime were products of normal learning processes, but the content of that learning differed.

Imitation and vicarious learning have been incorporated into the theory as well. If a person merely copies what others are doing, the process is referred to as *imitation*. Imitation is distinct from learning the normative standards appropriate to roles within a society or among groups (normative learning). If the learning process involves observation of the rewards and punishments experienced by others, the social learning mechanism is vicarious learning. If the learning process involves personal or direct experience of rewards and punishment as a product of one's own behavior, then

the process is one of differential reinforcements. Differential reinforcement refers to the general process of the individual's experience with and/or anticipation of the balance of positive and negative consequences of behavior.

Imitation is distinguished from differential association in that it refers to that part of the interaction in which one observes the behavior of others and the consequences of the behavior of the others. In brief, behavior is the outcome of differential association in which one is exposed to cultural or normative expectations and expressions, role models, and reward or punishment (including the reactions of others) attached to or following behavior. One's internalized attitudes are also an outcome of this same process and in turn serve as a *cause* or factor in the variations in overt behavior.

Research

Social learning theory has been subjected to more empirical inquiry in relation to a wider range of forms of deviance and in a wider range of settings and samples than any other criminological theory. Much of the research testing social learning theory has focused on its ability to explain variations in self-reports of lawbreaking behavior, especially among adolescents. Two perspectives have dominated comparative tests in criminology: social control and social learning. Social control theories assume that it is the absence of constraints or limits on opportunity for crime, which are key to the explanation of crime and delinquency. In such theories, the *motivation* for crime is found in characteristics of humans considered to be quite natural when social, cultural, or opportunity constraints are absent, implying that no special pressure is required. In contrast, social learning theories focus on normal learning processes, including socially structured schedules of reward and punishment; variable values, norms, and beliefs; and associations with people who both encourage and discourage crime and delinquency.

SSSL Theory

The social learning perspective has since been expanded to deal with both micro and macro issues, and Akers now labels the SSSL theory. In the SSSL approach, social learning is the principal mediating process by which social structure has consequences for criminal and delinquent behavior.

Social structural variables and factors are the primary macro-level and meso-level causes of crime, while the social learning variables reflect the primary or proximate causes of criminal behavior that mediate the relationship between social structure and the behavior of individuals that make up group, community, and societal crime rates.

This assertion is supported by research in which age, race, ethnicity, gender, social class, community, and region sociodemographic and community variables are inserted in empirical models. The findings typically are that the net effects of social learning variables remain in these models, while the net effects of sociodemographic variables are reduced, typically to statistical nonsignificance. For instance, several studies have found that variations by age and life course are largely accounted for by family socialization, peer associations, and other social learning variables. Tests of the SSSL model have produced positive findings for delinquency and substance use, elderly alcohol abuse, rape, violence, and binge drinking by college students.

New Directions

Other than replications and additional comparative tests, Akers and Jensen have outlined new directions for SSSL theory. One direction has been designated *Taking Social Learning Global*. The key development proposed has been to identify those mechanisms that can be designated as macro-level learning mechanisms that help explain international variations in homicide.

Another direction emphasizing macro processes in SSSL would be to explore the possible relevance of the logic of the theory to hypotheses about the relative salience of different forms of cultural learning to the explanation of variation in crime and/or different forms of crime. For example, from a social learning perspective, the violent resolution of interpersonal conflicts could be argued to become *normative* in environments where institutional means of conflict resolution have been scarce, where relations with institutional authority have been strained, and/or where escape from violent situations is difficult.

Another macro hypothesis reflecting the logic of SSSL is that the most common forms of criminal or delinquent activity will likely be those involving the most routine and ordinary learning processes. Shoplifting violates fewer normative

rules than purse snatching from an older lady. Robbing someone at gunpoint violates more normative rules than grabbing a bicycle from someone's driveway. Shoplifting is most probable when youth have the opportunity to do so, can manage such activity without generating suspicion, and have either learned rationales or excuses for such activity or not learned to judge such activity as a violation of norms.

SOCIAL SKILLS TRAINING

Social skills training refers to teaching individuals how to interact harmoniously with others, and especially how to maintain balanced and constructive behavior in difficult interpersonal situations. An individual may deal constructively with negative peer pressure by suggesting a responsible alternative activity, for example, or may calmly and sincerely offer a clarification or apology to an angry accuser. Social skills training programs typically apply to individuals with deficiencies in social interaction, such as children with attention-deficit/hyperactivity disorder or autism. This entry focuses on social skills

training for juvenile and adult offenders. Particularly noted is the use of virtual reality immersion therapy with *dual diagnosis* offenders, that is, adults with intellectual and developmental disabilities who have also committed felonies.

Social Skill Deficiencies

Many offenders evidence social skill deficiencies. Studies show that offenders low on measures of social skills commit more serious offenses; have a higher number of correctional facility placements, absent without leave (AWOL) attempts, and school absences; and self-report more substance and alcohol abuse. One study of peer-helping programs at juvenile correctional facilities found a paucity of practical social skills, such as how to take into account another's perspective. Without helping skills, the peer *helpers* readily resorted to counterproductive behavior, such as name-calling, profanity, screaming in the peer's face, and physical intimidation.

Training Programs

Social skills training programs seek to remedy such deficiencies and thereby reduce antisocial behavior. These programs generally explain to trainees that a social skill is learned the same way as one learns any skill. As with learning to ride a bicycle, swim, or play a sport, learning a social skill involves

- observing someone showing the skill (modeling),
- trying to imitate what was observed (enactment),
- finding out what one did right and wrong and how to do better (performance feedback), and
- trying again (practice) until the skill becomes habitual or automatic (second nature).

Such programs generally present social skills in concrete steps and emphasize social perspective taking in role-played and then actual, interpersonal situations. Social skills training pioneer, Arnold Goldstein, suggested that social skills should more accurately be called *social interaction skills*. This is to underscore the point that balanced perspective taking must apply not only to a single act but also across an ongoing interpersonal situational episode. He introduced a typology of

50 step-by-step social skills designed to promote an individual's ability to avoid aggression, reduce social tension or stress, deal with feelings, and plan ahead.

Equipping Youth to Think and Act Responsibly (EQUIP) and Responsible Adult Culture (RAC)

Social skills are taught, for example, in a treatment program for juvenile offenders called *EQUIP*, which was adapted for adults as *RAC*. *EQUIP* and *RAC* teach in a group context 10 social skills adapted from Goldstein's typology. These are

- expressing a complaint constructively,
- caring for someone who is sad or upset,
- dealing constructively with negative peer pressure,
- keeping out of fights,
- helping others,
- preparing for a stressful conversation,
- dealing constructively with someone angry at you,
- expressing care and appreciation,
- dealing constructively with someone accusing you of something, and
- responding constructively to failure.

A group leader discusses with the group how learning a social skill is like learning any skill and how these skills are useful. He or she encourages group members to think of difficult interpersonal situations where one of these skills would have helped. Group members can either provide a situation from their experience or select from a list of situations for the training. For the skill of expressing a complaint constructively, the list of sample situations includes items such as "You just found out who stole your sneakers" or "Your friend has spread a rumor about you."

Case Study

In the *EQUIP* program, a juvenile offender (Joe) learns the social skill of expressing a complaint constructively. Joe observes a group leader model the skill, tries to perform it, receives feedback from the leader and the group, and then practices the skill in increasingly diverse and challenging contexts. The skill is presented and modeled in four steps:

Step 1: Identify the problem. How are you feeling? What is the problem? Who is responsible for it? Did you contribute (or are you contributing) to the problem in any way?

Step 2: Plan and think ahead. To whom should you express your complaint? When? Where? What will you say (see step 3)?

Step 3: State your complaint. In a calm, straightforward way, tell the person the problem and how you feel about it. If you've contributed to the problem, mention how you may be partly at fault and what you are willing to do to improve the situation.

Step 4: Make a constructive suggestion. Tell the person what you would like to do about the problem. Ask the other person if he or she thinks your suggestion is fair. If the other person makes a constructive suggestion, say that you appreciate the suggestion or that it sounds fair.

After observing the skill as modeled by the group leader, Joe tries to role-play it in a difficult interpersonal situation: His father always wants to go to the bar instead of spending time talking to him. Going through the steps, Joe reports that he is feeling angry. His father is responsible for the problem, although Joe himself has contributed by trying to avoid it, for example, by "running off and partying" (Step 1). Joe plans to discuss it when his dad is at home and in a good mood and "say it in a polite way" (Step 2). A touching role-play follows. After acknowledging his own contribution to the problem, Joe constructively expresses the complaint to his *dad* (role-played by a fellow group member):

Dad, I would like to talk to you about how you like to go to the bar and not spend time with me. I feel that I am coming home from school and you are at the bar and I am upset about something. I want to talk to you and you are not there to talk to me.

Joe and his *dad* work out times when his father agrees to be at home and available (Step 3). Furthermore, *dad* agrees that Joe's complaint and suggestion are fair. Joe says he appreciates his father's responsiveness (Step 4). Joe's role-play performance is followed by feedback. The group and group leader tell Joe that he did

well on all the steps. Joe subsequently practices the skill in pertinent social situations, both inside the facility and outside, during permitted release periods.

Social perspective taking plays a major role in social skills training. In the example, Joe considered the moment when his father would be approachable, anticipated and accepted his father's likely viewpoint by acknowledging at the outset his own runaway behavior, listened openly to his *dad's* ideas as an understanding was reached, solicited his *dad's* feelings about the agreement, and expressed appreciation for the cooperation.

Critique

Social skills training programs have had mixed outcome results. Although some studies find gains in subsequent conduct or lower recidivism, other studies do not. A critic of such programs, the clinical psychologist Stanton Samenow, has argued that unless the offender's self-serving *thinking errors* (e.g., minimizing their harm to others or blaming their victims) are addressed, the treatment may only make matters worse. In other words, a criminal without social skills may merely learn how to become a criminal with social skills and hence more criminally effective. Samenow's critique is supported by the fact that the most successful social skills training programs have included corrective cognitive therapy. For example, EQUIP is a combined treatment program that includes not only social skills training but also an anger management component that features the correction of aggressogenic cognitive distortions (thinking errors). Other components of EQUIP and RAC include positive peer culture and moral judgment facilitation.

Virtual Reality Immersion Therapy

Worthy of note is a supplementary technique for helping offenders practice social skills. This technique can provide extra support and training where needed, such as among dual-diagnosis offenders. The technique, called *virtual reality immersion therapy*, provides an opportunity for these offenders to try out, practice, and observe their own social interaction skills within a virtual environment. A camera captures the trainee's live

image and immerses it in a computer-generated video display of a difficult interpersonal situation. The timing of when the trainee speaks is programmed by a computer. Contingent on the socially skilled or unskilled nature on the trainee's behavior, the therapist can activate prefilmed positive or negative responses in the virtual environment. Early results from the use of virtual reality immersion therapy in social skills training for dual diagnosis offenders are promising.

Future Directions

Despite their limitations, social skills training programs will likely continue to contribute to treatment approaches for offenders. The contribution of social skills training to offender treatment may be enhanced by its inclusion within cognitive multicomponent programs as well as by the use of supplementary techniques such as virtual reality immersion therapy.

SOCIOLOGICAL THEORIES OF CRIME

Sociological theories of crime focus on the criminal's relationship to others. The basic assumption underlying these theories is that criminals acquire their interests, skills, and the support for their actions through their interactions with others. Criminals are not responding to biological or psychological impulses. This entry examines a number of major sociological theories: anomie, strain, the Chicago School, and conflict theories.

Anomie Theory

Preceded by the social structure theories of Auguste Comte, Andre-Michel Guerry, and Adolphe Quetelet, anomie theory was developed by Emile Durkheim. For Durkheim, the word *anomie* was used to describe a state of normlessness. Anomie is caused by social change. Changes caused by the American and French Revolutions, the Industrial Revolution, and other significant societal events led to a disruption in the social order. According to the anomie theory, as the existing society loses its ability to maintain and balance societal needs and wants, the behavior of individuals goes unchecked and moral order declines.

Durkheim's ideas about crime grew out of his study of societal development, which focused on economics and the distribution of labor. The change from a simple agricultural-based society (i.e., mechanical) to a complex society that was the product of industrialization and the growth of urban areas (i.e., organic), as seen during the Industrial Revolution in Europe and North America, caused a state of normlessness or anomie. The social restraints of simple societies were broken by the vast anomies (i.e., increased social problems, especially criminal activity) of the newly urbanized areas. These broken restraints subsequently were the catalysts for a decline in moral order.

Crime is an outgrowth of this breakdown, and according to Durkheim, crime is normal and needed in all societies. Under the structural functionalist approach, crime has a purpose in society: Crime moral boundaries are *mapped out*, punishments for criminal acts increase awareness of what is unacceptable within society, and crime strengthens the social bonds of those whose

actions keep them within socially acceptable boundaries.

Crime is so important that within a crimeless society the definition of crime would need to be rewritten to assure that some individuals could be considered criminals. The overall purpose of redefining crime is group unity and group cohesion (i.e., criminals will be the agents of bonding for the greater society since the self-righteous will unite to combat the dysfunctional within the society).

Strain Theory

Strain theory assumes that humans are born innocent with good intentions. It is the society that causes individuals to commit criminal acts. Influenced by Durkheim, Robert K. Merton developed a strain theory connected to the time in which he lived. The Great Depression provided the backbone of Merton's theory as he focused on the influences of the American Dream in the United States. His ideas were based on his perceptions that the goal and means of pursuing the American Dream produced the *strain* that led to dissatisfaction and criminal behavior. The strain grew out of frustration that occurred when members of the lower socioeconomic classes realized that the American Dream was beyond their reach. Merton proposed five ways that individuals react to strain:

- (1) Conformity—These individuals accept the realities of their status.
- (2) Ritualism—These individuals simply go through the motions, setting new, less glamorous goals. (These groups have no desire or little motivation to commit crimes.)
- (3) Innovation—These individuals seek the goals of society, but their means are antisocial (i.e., criminal activities). (Not all innovators are criminals. Some use their creativity to seek the rewards of the American Dream by sidestepping traditional means.)
- (4) Retreatism—These individuals withdraw from society, subsequently abandoning all pursuits of and the desire for the American Dream.
- (5) Rebellion—These individuals seek to tear down and rebuild society on their own terms, establishing new goals and means.

Although Merton's ideas appeared sound during the Great Depression in the United States, as time moved onward and as society changed, his ideas came to be criticized by later scholars.

Merton's work was followed by the work of Albert Cohen in the 1950s and the work of Richard Cloward and Lloyd E. Ohlin in the 1960s.

Cohen's work focused on group formation. According to Cohen, disadvantaged youths are apt to experience failure because they have not been socialized to function within middle-class society. Failure elicits frustration, which causes strain. These individuals counter middle-class norms with delinquent behaviors that are anti-middle class.

Cloward and Ohlin's ideas are also linked to the American Dream. They believed that all social classes seek the values and norms that lead to the American Dream. Members of the lower socioeconomic classes who are blocked from socially acceptable approaches to obtaining the rewards of the Dream will experience frustration and strain. To counter this experience, these individuals will seek acceptance within one of three types of gangs:

- (1) Criminal gangs are structured, may be formed through adult criminal mentoring, and focus on crimes, of taking from others.
- (2) Conflict gangs exist in areas where there is less structure and no benefit from adult criminal mentoring; as a result, these gangs generally focus on violent, destructive behaviors.
- (3) Retreatist gangs are generally made up of members who failed to fit into society and criminal or conflict gangs. Their focus is to withdraw from society and focus on substance use to quell the frustration and strain that they experience.

A general strain theory was developed by Robert Agnew in the 1980s. Agnew broadened the scope of strain to include all socioeconomic levels. He believed people at all levels experience strain daily. He saw strain as being negative (i.e., noxious) or positive (i.e., valued).

Strain theory critics point out that various strain theories are dominant at specific times (e.g., the Great Depression, the 1950s, 1960s, and 1980s) and are rooted in the ideas and practices of their specific time frames.

The Chicago School's Theory

Just as Durkheim was inspired by the American and French Revolutions as well as the Industrial Revolution and Merton linked his ideas to what he and others observed during the Great Depression in the United States, the scholars of the Chicago School were motivated by the effects of rapid population growth and the urbanization of Chicago, IL. Along with the rise in population growth and urban expansion came a corresponding increase in poverty. These scholars viewed crime as a social ill that resulted from socialization that favored criminal behavior rather than that of the typical middle-class American family of the mid- to late-19th century to the early 20th century. The result of this environmentally influenced, crime-driven socialization process led to a breakdown in social institutions including families, schools, and communities. This breakdown has been termed *social disorganization*.

Robert E. Park and Earnest W. Burgess used ecological analysis to explore various aspects of social disorganization. They also focused on crime rates but did not focus on criminals. Park and Burgess developed a system of analysis consisting of five zones: Zone I—the central business district, Zone II—the transition zone, Zone III—the working-class homes, Zone IV—the area that included expensive homes, and Zone V—the suburbs.

Zone II seems to be the hotspot for the growth and development of social disorganization due to government-subsidized housing or government-run programs. This seems to be the area where people who cannot afford housing in Zones III, IV, and V end up living.

Conflict Theory

Conflict theorists are interested in the study of conflicts among various socioeconomic groups, especially as these groups struggle over power, the distribution of resources, and inequality.

Karl Marx noted that the poor and members of the working classes were arrested and charged, found guilty of crimes, and incarcerated at a rate that surpassed that of the upper classes. Law becomes a means of controlling the less fortunate whose numbers are vastly superior to the middle and upper classes combined. The bourgeoisie (i.e., upper classes) keep the proletariat (i.e., lower classes)

from sharing in the wealth and power, assuring that they will be the dominate force within society.

Laws make resistance to authority and the struggle for equality a crime. As with other social scholars, Marx saw crime as the result of a dysfunction with society. He saw the seemingly endless pursuit of capitalism and the sanctioning of inequality as the catalyst for crime.

George Vold basically noted that humans are social beings; therefore, they work collectively to survive. As societies flourish and expand, various groups begin to compete for power. This competition leads to conflict, especially as groups seek to control the political power within their society. The groups in power create and enforce laws that suppress the efforts of the less powerful with society. Vold reasoned that by using power to suppress others, the dominant group was equally guilty of committing criminal acts. However, Vold saw that conflict could lead to a state of equilibrium (i.e., compromise would bring about social and political stability).

Austin Turk, like other conflict theorists, saw competition among groups as the catalyst for crime. Turk stands out because he looked at the role of the criminal justice system in maintaining the status of those in power. Laws are created, enforced, and maintained as a means of controlling the less powerful within society and of supporting the position and authority of the power elite. For Turk, crime is not the result of biopsychological impulses. For Turk, crime is a method of determining how the criminal justice system can classify and treat someone based solely on his or her social status.

SPECIALTY COURTS

Specialty courts, also referred to as *problem-solving courts*, have specially designed dockets that address one type of criminal offender. In a 2016 document titled *Specialized and Problem-Solving Courts*, published by the National Institute of Justice, it was noted that these courts focus their attention on offenders whose criminal activity stems directly or indirectly from one or several problems related to drug abuse, mental health, family adjustment, or other criminogenic issues. Typically, the defendants who appear before specialty courts will receive a sanction that addresses the source of the problem (e.g., drug abuse, mental health, family abuse) that resulted in their criminal behavior. The sentencing judge and other criminal justice personnel as well as social service workers play a critical role in the supervision and treatment of those offenders under the court's jurisdiction. This entry first discusses the concept of diversion in the justice system and then reviews several types of specialty courts, including mental health courts, drug courts, domestic violence courts, community courts, and veterans' courts.

Diversion

Research on convicted criminals completed during the late 20th and early 21st centuries revealed that a large proportion of those sentenced to jails and

prisons throughout the United States could have been diverted to some form of community supervision without posing any threat to the security of the community. The majority of those eligible for diversion are in need of some form of treatment as a result of having mental health, substance abuse, or family adjustment problems.

The term *diversion*, when applied to the justice system, refers to any method used to move a person, either juvenile or adult, who has allegedly committed a criminal offense away from formal court processing. Diversion occurs when some action is taken by a justice agent, usually a police officer, in which the person is referred to a nonjudicial agency or to a specialized court rather than being referred to the traditional courts for processing. The decision to divert a certain offender is either based on the arresting officer's discretion, the prosecutor's office, policies of the agency, or the statutes of the state or local government. Offenders most likely to be diverted from the criminal justice system are those who have committed minor offenses, those with mental illness, elderly offenders who have committed minor offenses, those who are homeless, and alcohol and substance abuse offenders.

Mental Health Courts

In 2015, there were over 11 million admissions to U.S. jails and lockups. The jails in the United States, particularly those located in large metropolitan areas, tend to be overcrowded and dangerous for both inmates and correctional staff.

Concern over incarcerating those who are mentally ill has increased nationwide. It is not known what proportion of those held in jails have mental health problems. A National Initiative to Reduce the Number of People with Mental Illnesses in Jails was launched in 2015 by the Council for State Governments Justice Center and the American Psychological Association Foundation. This initiative was designed to rally support for achieving a reduction in the number of people with mental illness in jails. Programs that address this initiative can be found throughout the United States.

The police working in many counties throughout the United States, particularly those that have a relatively small population, face a dilemma when they encounter a law violator whose

behavior shows signs of mental illness. Although, the police realize that arresting the person and transporting the person to jail is not the ideal course of action, it is often the only option available since the community may not have other means for dealing with such cases. In making a decision to arrest or divert mentally ill persons they encounter, police officers also have to consider the potential for the mentally ill person to become violent and thus pose a danger to the community. Although a lack of resources in the community may be the primary reason for not diverting mentally ill criminal offenders away from jail, poor coordination and distribution of available resources are also reasons why many mentally ill offenders (particularly those who have committed nonviolent misdemeanors offenses) may end up in jail rather than in a facility with staff and resources to deal with offenders who exhibit some form of mental illness.

Federal and state grants to local criminal justice agencies have helped to fund police and court diversion programs. This has led to the development of mental health courts throughout the United States. The Council for State Government Justice Center describes the characteristics of mental health courts as those courts that employ a problem-solving approach to court processing of offenders in place of the more traditional court procedures that often result in defendants with mental health problems being incarcerated in jails or prisons.

Mental health courts were developed in the latter part of the 20th century to meet the needs of the millions of criminal offenders processed through the justice system each year who have some form of mental illness that directly or indirectly relates to their criminal behavior. The American Law Enforcement and Mental Health Project was created by the U.S. Congress in 2000. This legislation provided funding for the development and implementation of mental health courts. As a result, the number of mental health courts increased significantly in the ensuing years.

A survey of mental health courts found that the political jurisdictions included in the research received funding from a number of sources, including dedicated county funding, federal grants, local mental health funding, and in-kind contributions from local health-care agencies. Authors of

the survey concluded that, typically, mental health courts are judicially administered in a specific community. They utilize court staff and professionals who treat patients with mental health problems in the development and implementation of a treatment plan that addresses the needs of the offender as well as those of the community. Referrals to mental health courts can originate from several sources, including the judge, county or state prosecutor, public and private attorneys, social service agency personnel, and even family members.

The treatment programs included in this survey provided incentives for program completion. The most common was to drop or suspend the criminal charges. Participants were required to attend court sessions before the mental health court's judge. Generally, their participation in some form of counseling and contribution of a specified number of hours of community service were required. Those who successfully completed the program participated in a graduation ceremony held in the courtroom. Those who did not complete the program for reasons related to recidivism, failure to complete the requirements, or other reasons were terminated from the program and sanctioned.

Each mental health court functions independently within its own district, but the mental health courts have similar characteristics and goals that make them different from the typical criminal courts. These characteristics are as follows:

- Each court requires voluntary participation, so the defendant must consent to be a part of the program and consent to treatment.
- Each court has eligibility criteria, all include mental illness as defined by the *Diagnostic and Statistical Manual, Fourth Edition, Text Revision*, and some include developmental disabilities and traumatic brain injury as possible qualifiers for participation in mental health court.
- Mental health courts employ legal and mental health professionals to address a specialized docket that focuses solely on preventing incarceration of mentally ill individuals, offering court-mandated treatment as an alternative.
- Mental health courts place public safety in the highest regard when considering treatment or housing options for mentally ill offenders.
- In general, most mental health courts offer a higher level of supervision, requiring clients to attend regular status hearings to assess the progress of treatment and to update treatment plans.
- Finally, most programs have defined criteria for completion of the program, marked with a graduation or certificate of completion.

Drug Courts

The implementation of drug courts was spread throughout the United States during the late 20th century and early 21st century. These specialty courts required those who were brought before the drug court judge as a result of being charged with a drug-related offense (alcohol included) to agree to participate in a program that provided sanctions as well as treatment.

The drug court movement was stimulated by the passage of the Violent Crime Control and Law Enforcement Act in 1984. This act provided funding to local jurisdictions to set up community-based programs for drug-using offenders. The drug courts that were developed varied in structure and operation but tended to have several common characteristics. To be eligible for the drug court, the offense was required to be drug related. Participation was voluntary, that is, the defendant had the option of being tried in the drug court or in the regular criminal court, and the determination of the guilt or innocence of the charge would be deferred. If the person successfully completed the program, then the charges could be dropped. The presiding judge of the drug court had wide discretion in deciding who is eligible for the court (generally violent offenders are excluded) and what type of sanctions and treatment program the defendant would be required to complete. The supervision and treatment programs that the drug court participants are involved in are staffed by both court officials (probation officers) and mental health professionals such as psychologists, counselors, and social workers.

The evaluation of the success of drug courts is very difficult since criteria for referral eligibility to the courts are often quite different. For example, some courts accept only defendants who engaged in a drug-related felony crime. Others generally exclude defendants charged with a felony-level

crime, particularly if the crime involved violence. The resources for the treatment portion of a drug court program can make a difference on the likely success or failure of the participants. Also, the characteristics of the participants and the support systems they have (i.e., family support, steady employment, community support) will have an effect on the outcome.

The manner in which success or failure is defined is important and should always be considered when deciding if the program should be continued. One of the requirements of drug court participants is that they periodically appear before the presiding judge in open court and discuss their progress in the program. The judge will question them on the degree to which they have made progress toward fulfilling the conditions set by the court, such as finding employment, the use of drugs, the completion of the community service required, and other factors pertaining to the fulfillment of the conditions set by the court.

Domestic Violence Courts

Specialized domestic violence courts were first established in the 1990s. The specific goals of these courts were to process domestic violence cases quickly and efficiently, to ensure more consistent rulings and case follow-ups, to ensure that the offenders are held accountable for their acts, and to incorporate a stronger focus on the treatment of the offender deterring future offending.

As with other problem-solving (specialty) courts, domestic violence courts tend to be based on theories and practices grounded in therapeutic jurisprudence. That is, domestic violence courts focus on the needs of those involved, including those of the perpetrator of the violence, those of the victims of the violence, and the needs of the community in which the violence occurred. Rather than following the traditional adversarial process in the judicial proceedings, a problem-solving orientation is employed. Several domestic court models have been delineated to include the following:

- The *dedicated civil protection order docket model* handles only civil protection orders. Under this model, a court and judge are dedicated to hearing and making determinations on civil domestic violence matters.
- The *criminal model* segregates the domestic violence cases into one specialized court, with the judge being specialized in domestic law. In some jurisdictions, a single court can hear both misdemeanor and felony domestic violence cases, but in other jurisdictions, there are separate courts for the misdemeanor and felony cases. The integrated model handles both criminal domestic violence cases and related civil matters.
- In the *Unified Family Court*, one judge handles all matters related to the family. In addition to domestic violence, this court handles protection orders, dissolution custody, juvenile delinquency, paternity, and child dependency resulting from abuse and neglect.

Research revealed that the existence of a specialized domestic violence court led to an increase in the law enforcement responsiveness to domestic violence and a reduction of recidivism of domestic violence offenders. In addition, by having all domestic violence cases processed through one specialized court, there was better coordination of resources, supervision of defendants, and consistency in case processing

Community Courts

Another example of the trend toward diverting some categories of criminal offenders rather than processing them through the criminal justice system is the implementation of community courts. As the name implies, *community courts* are problem-solving courts that attempt to address some of the community's crime-related problems such as theft, property destruction, vandalism, and public safety needs through court intervention at the local community level. This is accomplished by way of an integrated community response to the safety of the community and the quality of life problems that are caused by those residents of the community committing crime.

Community courts do not concentrate on one specific problem area as is the case with drug courts, mental health courts, and family violence courts. However, the goals are similar to the goals of those courts in that there is an attempt to develop communications between the judiciary and the community, and there is an attempt to

provide the sanction that will be beneficial to the offender, the victims, and the community. In addition, social and psychological assistance is provided when needed.

The structure, administration, and goals of community courts may differ. However, most community courts have several key features:

- *Individualized Justice*—Community courts base judicial decision-making on access to a wide range of information about defendants.
- *Expanded Sentencing Options*—Community courts have available enhanced range of community and social service diversion and sentencing options, some of which involve referrals to community-based providers. Community courts seek a reduction in conventional sentences such as jails, fines, and time served.
- *Varying Mandate Length*—Community courts develop a multitrack system, in which a (typically small) proportion of defendants receive medium- or long-term judicially supervised treatment for drug addiction, mental illness, or other problems, while the majority of defendants receive short-term social or community service sanctions, typically 5 or fewer days in length.
- *Offender Accountability*—Community courts emphasize immediacy in the commencement of community or social service mandates and strict enforcement of those mandates through the imposition of further sanctions in response to noncompliance.
- *Community Engagement*—Community courts establish a dialogue with community institutions and residents, including obtaining community input in identifying target problems and developing programs.
- *Community Impacts*—Community courts seek community-level outcomes, such as reductions in neighborhood crime or repairing conditions of disorder through community service.

As one example, the Midtown Community Court was established in 1993 through the joint efforts of community leaders, neighborhood residents, and justice officials in New York City. This court deals with community disruption crimes

such as prostitution, illegal vending, vandalism, destruction of property, and theft.

This court provides a quick response to those involved in such offenses by having the cases heard as soon as possible and giving appropriate sentences that fit the nature of the crimes and needs of the offenders. For example, offenders are required to provide community service by cleaning subway stations, cleaning streets and parks, or removing graffiti from public buildings. The court could also order drug treatment and health-care education for those who need such assistance.

Research on community courts indicated that outcome goals of establishing community engagement, providing alternative sanctions, reducing costs, and engaging the defendants were largely achieved. The research showed that a majority of defendants received alternative sentencing such as a community service mandate and were given jail time primarily as a secondary sentence if the defendant failed to complete the requirements of the original sentence. The court provided individualized treatment, and those who needed special services, such as drug treatment, were required to participate in a treatment program as a condition of their sentence.

Veterans' Courts

Veterans' courts are similar to community courts in that they are not directed toward addressing a specific offense but directed toward a specific category of offenders, that is, military veterans.

The criteria for eligibility to a veterans' court vary in accordance with the laws established in the state and local jurisdiction in which the court is established. Typically, standard features of veterans' treatment courts are required court appearances at times specified by the court, mandatory attendance at the treatment sessions ordered by the court, drug and alcohol testing for those with a substance abuse problems, and submitting to outcome assessments. As with other specialty courts, those selected for veterans courts have an option of having their case docketed in a veterans' court or having their case processed in the traditional criminal court.

A benefit of such courts for veterans is that they appear before a judge who understands the sources of their problems, that is, how their

experiences in the military influence their actions that led to their criminal justice involvement. In addition, the judges and staff of the veterans' treatment court have established cooperative relations with the Veterans Health Administration, Veterans Benefits Administration, and with state departments of veterans' services. The veterans brought before the court who are in need of physical or mental health services are referred to appropriate agencies.

Final Thoughts

There were several influences leading to changes in criminal justice philosophy and laws that led to the development of specialty courts. The cost of holding impaired offenders in jail and in long-term correctional institutions is prohibitive; there is considerable evidence that the punishment received did more harm than good to the inmates, their families, and the community; the type of treatment that such offenders needed to eliminate or reduce the effects of their problems was generally not available in the correctional facilities; and the prediction that those offenders with mental health problems and drug abusers would in some way pose a special threat to the security of the community just did not materialize.

With the help of federal, state, and local funding, justice agencies were able to establish specialty courts such as mental health courts, drug courts, veterans' courts, and community courts. All of these specialty courts rely on community resources and cooperation from various service agencies to provide the type of treatment offenders with special problems need.

SPIRITUALITY

Spirituality concerns ways of living in relation to, believing in, and valuing the immaterial aspects of existence. In Western tradition, it has been historically associated with religious faith involving core beliefs in a divine, causal intelligence (i.e., a god) and a soul (i.e., an incorporeal, personal essence). As the United States becomes multicultural, non-Western religions have contributed to emerging concepts of spirituality. In today's diverse, secular society, spirituality may also proceed from a humanistic perspective. Atheists or agnostics, as well as persons of faith, may dedicate themselves to the well-being of others through investment in ideals and principles, lifestyles, political causes, and/or faith in science as a means of improving the human condition. Spiritual beliefs offer purpose, community, and meaning to followers and provide comfort and solace to many adherents in difficult circumstances. Spiritual leaders may be ordained clergy, teachers (e.g., gurus), political figures, or those promoting human and civil rights or environmental causes. This entry addresses the history of Western spirituality and then examines the relationship of spirituality with both science and the criminal justice system.

Early History: Spirituality and the West

From Religious Orthodoxy to Pluralism

In polytheistic Greece, Plato (*ca.* 427–347 BCE) spoke of the immortal soul and the reward after death for a virtuous life guided by philosophy. According to tradition, the three major monotheistic religions, Judaism, Christianity, and Islam, originated with the patriarch Abraham. Beginning as a Jewish sect in the Roman Empire during the 1st century CE, Christianity became a separate messianic religion whose members were regularly persecuted and often executed for their faith. Orthodox Christianity deified its object of veneration, Jesus of Nazareth, and taught scripturally based codes of belief and conduct, whereby sin and virtue were judged, with the soul's eternal salvation or damnation hanging in the balance. After the Emperor Constantine (*ca.* 280–337) was converted, Christianity received favored status (327) within the Roman Empire. The church, in turn, supported the Emperor's secular legitimacy. Over time, distinct, albeit mutually supportive, spheres of church and state developed in the western part of the empire. Church courts in early modern Europe had limited jurisdictional authority, varying by country, in concert with the state. Punishments meted out by ecclesiastical courts were often mild, including public penance, although death sentences were occasionally imposed, notably by the Inquisition.

Beginning in the early 17th century, settlers representing a range of Protestant denominations began colonizing North America, promoting religious toleration. Among these were the Quakers, or the Society of Friends, whose members became involved in many social causes, including prison reform.

Psychiatry and Spirituality

From the late 17th century, persons in England and France claiming direct communication with God began coming under the scrutiny of the emerging field of psychiatry. Their behavior was increasingly seen as symptomatic of madness rather than as the overt manifestation of supernatural forces. An overemphasis on religious exhortation was even seen as potentially exacerbating madness. Moral treatment, or moral therapy, for the insane, a humane practice partly derived from religious pastoral care, and promoted by such luminaries as Philippe Pinel

(1745–1826) in France and the Tukes, a lay Quaker family, in England, replaced, at least temporarily, more punitive, restrictive forms of treatment. Similarly, madness became a basis in modern law for exculpating some criminal defendants (*i.e.*, the *not guilty by reason of insanity* verdict).

Faith, Science, and the Penitentiary

The Enlightenment era gave rise to a belief in the ability of controlled environments to shape behavior. A new type of prison called the *penitentiary*, dating from the late 18th century, was intended not only to punish but also to rehabilitate offenders. With considerable influence from the Quakers in Philadelphia, penitentiaries were designed to promote introspection by isolating the inmates, leading to self-examination and reform, and thereby inducing them to embrace law-abiding lives upon release. Although these institutions were unsuccessful in this respect, spirituality has continued to be an integral part of the American criminal justice system.

Spirituality, Science, and the Modern American Criminal Justice System

Spirituality in a Changing World

The spiritual landscape of the United States is changing. As of 2014, about 76% of all Americans described themselves as affiliated with some formal religion, with the great majority endorsing one of the Christian denominations. However, the number of persons characterizing themselves as Christians fell from the previous survey in 2007 (from 78.4% to 70.6%), while those identifying with non-Christian faiths or claiming no affiliation (*e.g.*, atheist or agnostic) increased over the same period (4.7–5.9% and 16.1–22.8%, respectively).

In the context of global promotions of human rights, notably the United Nations Universal Declaration of Human Rights, passed in 1948, spirituality in the latter half of the 20th century underwent a marked shift. Increasingly, it was based on adherence to values and beliefs apart from organized religion. Similarly, a *third force* emerged within psychology, differentiated from the psychoanalytic and behavioral schools, emphasizing the entirety of human experience, including needs unique to each individual (*e.g.*, self-actualization).

The 1960s marked a sea change in American culture due in large measure to a youth movement, the counterculture, characterized by experience seeking and sometimes militant protest. Many members of that age cohort embraced psychoactive drugs, particularly hallucinogens, and/or practices derived from Eastern religions, including meditation, as nontraditional paths to enlightenment and spiritual growth. Since the 1960s, the nation's racial and ethnic demographics have also changed considerably. Consequently, contemporary spirituality is a more heterogeneous concept, having both traditional religious and secular elements, consistent with the United States' growing multiculturalism. This has been reflected in American jails and prisons, where the percentage of prisoners professing non-Christian faiths exceeds that in the adult general population.

Spirituality and Government

Since the latter half of the 20th century, there has been a contentious relationship between groups who want more religion in public life and those who insist on a greater separation between church and state. The 1962 U.S. Supreme Court decision in *Engel v. Vitale* (370 U.S. 421) blocked compulsory school prayer. However, the evangelical Christian movement brought new energy to initiatives such as the teaching of creationism in public schools as an alternative to the theory of evolution, and opposition to abortion, which had been legalized in 1973 by the Supreme Court's *Roe v. Wade* (410 U.S. 113) decision. The White House Office of Faith-based and Neighborhood Partnerships was established by President George W. Bush in 2001 and was continued during the Obama administration. Its mission is to provide care and services for needy Americans through partnerships between government and faith-based as well as secular non-profit organizations. Mirroring this trend was the passage of the Religious Freedom Restoration Act of 1993 and the Religious Land Use and Institutionalized Persons Act of 2000, which strengthened prisoners' rights to exercise their religious beliefs.

Spirituality, Science, and Rehabilitation

Notions of the self (i.e., consciousness and free will), and therefore of spirituality, have been

called into question by data from the field of neuroscience. Studies with patients undergoing callosotomies (i.e., *split-brain* operations) demonstrated that consciousness was not a unitary phenomenon. It has been shown that motoric behavior occurs prior to conscious awareness of the action.

However, there has been a shift in some quarters away from reductive theories of positivism and radical behaviorism that were popular in the mid-20th century and toward an integrated science of mind which accommodates consciousness, free will, and personal responsibility, and thus religious belief. The impact of Buddhist teaching is evident in the increased interest in and study of interventions such as mindfulness.

As of 2014, there were more than 2 million persons in U.S. jails and prisons. The right of inmates to participate in religious services, including those of the so-called pagan religions (e.g., Wicca), of their choice is legally guaranteed. Most federal prisons make sweat lodges available to Native American inmates for their religious practices. State and federal prisons typically have one or more full-time chaplains or religious services coordinators to accommodate the needs of the inmates.

Interventions with spiritual, sometimes formally religious, components continue to be a part of the U.S. corrections system. Of particular relevance is Alcoholics Anonymous, the 12-step program premised on a belief, broadly construed, in God. The Federal Bureau of Prisons operates the Life Connections and Threshold Programs. These are in-prison, faith-based programs that also support community reintegration and are available to inmates throughout the federal prison system. Prisoner visitation programs include those operated by Prisoner Visitation and Support, an interfaith agency grounded in Quaker tradition, and Prison Fellowship, an evangelical Christian organization. The Aleph Institute offers a range of services to Jewish prisoners, including rabbinical prison visitation. Other organizations offer a range of services, from visitation to meditation classes and instructional materials, derived from Eastern religious traditions. Since the 1990s, mindfulness, based on Buddhist meditation techniques, has been adopted by mainstream clinical psychology. Whether mindfulness will be successfully adapted for use in correctional rehabilitation programs remains to be seen.

Spirituality and Resistance

The Judeo-Christian tradition has long been associated with enduring oppression through faith. The Israelites of the Old Testament were subjected to slavery in Egypt before their escape, and the central figures of the New Testament, particularly Jesus of Nazareth, were arrested, imprisoned, and executed for their faith. Several of St. Paul's epistles were supposedly written while he was in prison in Rome. In modern times, spirituality was a means of coping with the horrors of the Holocaust in Nazi Germany.

Civil disobedience, an integral part of American political protest since the mid-19th century, has continued to the present. At the forefront of the American civil rights movement of the 1950s and 1960s were several members of the clergy. The Rev. Martin Luther King Jr. and the Rev. Ralph Abernathy were among those arrested and jailed for protesting racial discrimination laws in the South.

The prisoner rights movement was also ascendant in the United States during the 1960s, supported by the growth of the Black Muslim sect as more and more African American males were being incarcerated. This state of affairs offered a competing narrative to the traditional notion of individual pathology as causing criminal behavior, reframing criminality in terms of class/race oppression. Where the mental health establishment might label prisoners as *antisocial*, a growing awareness of solidarity, in some cases spiritually based, permitted prisoners to view themselves as victims of societal bias. After the terrorist attacks on the World Trade Center and Pentagon on September 11, 2001, there was a heightened concern about the potential of Islamic radicalization among American prison inmates—a contemporary form of spiritually based resistance, and to prison administrators, a potential management concern. However, as of 2016, there is little evidence of a significant security threat within or beyond prisons from inmates espousing radical forms of Islam.

SPOUSAL ASSAULT RISK ASSESSMENT (SARA)

The SARA is a structured clinical judgment screening tool used by clinicians, mental health providers, and other professionals to evaluate the risk of future violence in persons who are accused or convicted of spousal assault or intimate partner violence (IPV). The SARA was developed by the British Columbia Institute Against Family Violence, the British Columbia Forensic Psychiatric Services Commission, and several other agencies as part of the Project for Protection of Victims of Spousal Assault. After a brief discussion of IPV in today's society, this entry focuses on the uses, completion process, and reliability and validity of the SARA.

IPV

IPV is prevalent in today's society. According to the U.S. Centers for Disease Control and Prevention's 2014 *Understanding Intimate Partner Violence Fact Sheet*, every minute, 24 people are victims of IPV, including more than 12 million

men and women each year. IPV is associated with psychological distress, poor cognitive functioning, depression, drug and alcohol abuse, and suicide. The 2010 *National Intimate Partner and Sexual Violence Survey* reported that approximately one in four women and one in 10 men who have experienced IPV report short-term and long-term symptoms of post-traumatic stress and other emotional difficulties. For these reasons, risk assessment tools, such as the SARA, are in high demand to aid in the management and treatment of the offender and to reduce the likelihood of recidivism.

Completing the SARA

Accurate completion of the SARA requires collecting a large amount of data on the client, including interviewing the defendant/offender, and victim; completing standardized measures of physical and emotional abuse as well as standardized measures of alcohol and drug abuse, reviewing collateral information (e.g., police reports, criminal offense records); and using other psychological assessment procedures (i.e., personality inventories, cognitive testing and clinical interviews with children, relatives, and/or probation officers). Suggested standardized measures are included in the user's manual.

After completing these procedures and measures, the clinician rates the client on 20 items on a 3-point scale (0 = *absent*, 1 = *possible or partially present*, 2 = *present*), which are grouped into four risk areas: criminal history (i.e., history of assault), psychosocial adjustment (i.e., mental disorders, recent stressors), spousal assault history, and elements of alleged/most recent offense (i.e., use of weapon). The overall risk designation is determined by the clinician and not necessarily tied to the sum of the items. Also contained within the SARA is a section titled Other Considerations that allows for the clinician or mental health professional to note important risk factors not incorporated within the SARA. The user's manual includes the scoring instructions.

Uses of the SARA

The SARA has been used throughout various stages of the criminal justice process. The SARA

can be used during the pretrial phase to assist the judge in determining whether the accused should be granted pretrial release. If the accused is seen as a threat to his or her spouse and/or others, the individual may not be granted bail. The SARA can also be used during the presentencing phase when the judge is determining the sentence or discharge.

Correctional personnel can use the SARA to evaluate the individual and develop an appropriate treatment plan. Correctional personnel may set conditions, such as visitation restrictions or temporary absences, based on their findings. When the offender is being discharged, the SARA can help correctional personnel or parole officers determine the discharge conditions and aid in postrelease treatment and management. The SARA's usefulness is not limited to the criminal justice system but may also serve as a tool in civil cases such as custody agreements and divorces.

Reliability and Validity

Although the SARA is not a psychological test, it is important to evaluate its reliability and validity as an assessment tool. Since it is designed to assess risk of future behavior, interrater reliability is a significant issue. Interrater reliability refers to the degree to which two or more individuals agree on the ratings of a certain phenomenon.

In a study conducted in 2000 on two large groups of adult male offenders ($N = 2681$), P. Randall Kropp and Stephen D. Hart tested the interrater reliability of the SARA. Interrater reliability was high across correctional officers who had extensive experience and background dealing with these cases and doctoral graduate students who based their opinions on the case history information provided. Intraclass correlation coefficient for total score and number of factors present were .84 and .83, respectively. Intraclass correlation coefficient for summary risk ratings based on low-, moderate-, and high-risk classification by clinicians was .63. The raters agreed in 69 of 86 cases (80%), and no extreme disagreements existed where an accused person received a high-risk rating and a low-risk rating from two different individuals.

The researchers also found that the SARA had moderate concurrent validity with the Psychopathy Checklist–Screening Version ($r = .43$ for total

score and $r = .34$ for the summary risk rating). Concurrent validity refers to how well the scale correlates with other tests measuring the same or similar construct. In 2004, Kirk R. Williams and Amy Barry Houghton also found statistically significant correlations between the Domestic Violence Screening Instrument and the SARA for both total scores ($r = .54$) and the summary risk rating ($r = .57$; $n = 434$). In 2008, N. Zoe Hilton and colleagues found moderate to large correlations between SARA total scores and a variety of assessments of psychopathy and risk of violence.

The SARA total score has similar predictive validity when compared with several other IPV risk assessments using the receiver operating characteristic area under the curve (AUC). Predictive validity refers to the likelihood of future events. When compared to the Ontario Domestic Assault Risk Assessment (AUC = .666, $k = 5$), the Danger Assessment (AUC = .618, $k = 4$), the Domestic Violence Screening Inventory (AUC = .582, $k = 3$), and the Kingston Screening Instrument for Domestic Violence (AUC = .537, $k = 2$), the SARA (AUC = .628, $k = 6$) scored the second highest on the AUC measure for predictive validity.

STABLE-2007 AND ACUTE-2007

The prediction of sexual recidivism is one of the most difficult tasks in forensic psychology since human behavior is dependent upon a variety of different factors. Yet assessing risk of recidivism in sexual offenders is an important societal and legal issue because it guides decisions concerning public safety and adequate treatment planning for sexual offenders. Two actuarial risk assessment instruments (ARAIs), the Stable-2007 and the Acute-2007, encompass risk factors that are able to change slowly (i.e., stable) or quickly (i.e., acute) and are therefore amenable for offender treatment programs to reduce the risk to sexually reoffend. By assessing dynamic risk factors, the Stable-2007 and Acute-2007 predict the probability to reoffend in adult male sexual offenders. This entry provides a snapshot of recidivism risk prediction and static and dynamic risk factors, then focuses on the Stable-2007 and the Acute-2007, their development as well as their items, scoring, and validity.

Actuarial Prediction of Recidivism Risk

In order to predict the recidivism risk of sexual offenders, clinicians started to assess offenders based on their subjective experiences after some personal contact with the person concerned. However, Paul E. Meehl demonstrated in 1954

that intuitive judgments, even if they were conducted by experienced clinicians, performed not better than by chance. Meehl revealed that explicitly defined risk factors (e.g., the number of previously committed crimes) that were empirically linked to an increased recidivism risk were more accurate than intuitively established clinical risk factors. He defined the former as the actuarial method of prediction, which has at least two main characteristics: First, there is an explicit rule of combining risk factors (e.g., summing up all scores to one total score), and second, this sum is linked to an empirically derived probability figure (e.g., the probability to reoffend). Structured prediction methods, especially actuarial methods, are state-of-the-art tools in the prediction of recidivism risk in sexual offenders.

Static and Dynamic Risk Factors

Every ARAI consists of a number of risk factors that have to be combined in an explicit manner. These risk factors have different characteristics related to their stability over time. Risk factors are categorized as static or dynamic depending on whether or not they are potentially prone to change. *Static risk factors* are characteristics of an offender, which are unchangeable, such as the criminal history (e.g., the number of prior offenses) or victim characteristics. Static risk factors provide information about the status risk of an offender compared to the population he belongs to. Due to their clear operationalization, static risk factors can be easily rated based on file information, which leads usually to a high interrater reliability of these ARAIs. *Dynamic risk factors* are amenable to change and can be further divided into stable or acute dynamic risk factors depending on the rapidity of change. *Stable dynamic risk factors* last usually longer time periods (e.g., months or years), but they could be potentially modified, for example, by treatment. Examples of stable risk factors are risk-related traits (e.g., lack of concern for others or impulsivity), sexual self-regulation deficits (e.g., sexual preoccupation or deviant sexual interests), or intimacy deficits (e.g., emotional identification with children or loneliness). *Acute dynamic risk factors* are factors that could rapidly change and are therefore conceptualized as immediate warning signs of an impending risk to commit a crime.

Examples of acute risk factors are victim access, substance abuse, or the collapse of the social support system.

The research and proliferation of static risk factors as well as the development of ARAIs consisting of stable and acute dynamic risk factors were strongly influenced and supported by the Risk-Need-Responsivity model of offender rehabilitation, which indicated that an effective intervention has to focus on risk (i.e., the risk potential of the single offender for committing new offenses), need (i.e., consideration of empirically proven criminogenic needs in terms of particular treatment goals), and responsivity (i.e., the use of intervention techniques and treatment programs to which the individual offender's abilities, learning style, motivation, and strengths respond).

The use of ARAIs can be regarded as an important component of effective offender rehabilitation because it contributes to an accurate measure of the individual level of risk by using static risk factors (i.e., risk principle) and by defining treatment targets in terms of criminogenic needs by using stable and acute dynamic risk factors (i.e., need principle). Currently, the most widely used series of actuarial sexual offender risk assessment instruments are the *Static-99*, which consists of 10 static, historical, and biographical risk factors; the *Stable-2007*, which consists of 13 stable dynamic risk factors; and the *Acute-2007*, which consists of seven acute dynamic risk factors.

The Development of the Stable-2007 and the Acute-2007

These two instruments were developed to assess dynamic risk factors in order to predict the probability to reoffend in adult male sexual offenders. There have been three empirical steps in the development of the current versions of the *Stable-2007* and the *Acute-2007*.

The predecessor of both instruments, the Sex Offender Risk Assessment Rating, was developed by Karl Hanson and Andrew Harris within the Dynamic Predictors Project that spanned from 1996 to 2004. In this project, the researchers compared 208 sexual offenders who reoffended during their time on community supervision with 201 offenders who did not reoffend during that time period. When investigating the differences between

these groups, they found two different types of dynamic risk factors: stable and rapidly changing factors. Therefore, the Sex Offender Risk Assessment Rating implied five stable and four acute dynamic risk factors.

In the second step, Hanson and his colleagues revised the Sex Offender Risk Assessment Rating due to conceptual and clinical concerns by separating stable and acute items into two distinct measures, the Stable-2000 and the Acute-2000. Additionally, the items of the Stable-2000 were further embedded in a more psychologically sound theory. A manual provided clear operationalizations and definitions of all items as well as explicit scoring details. The Stable-2000 comprised six risk areas: significant social influences, intimacy deficits, sexual self-regulation, general self-regulation, cooperation with supervision, and attitudes supportive of sexual offending. The final score results from the highest score of an item within each risk area. The Acute-2000 contained 8 items: seven general risk factors and a unique risk factor which should capture risk-relevant information only applicable in the individual case.

In the third step, Hanson and colleagues started a study in 2007 by using a prospective-longitudinal research design, the Dynamic Supervision Project. Parole and probation officers in Canada, Alaska, and Iowa were trained in the administration of the Static-99, the Stable-2000, and the Acute-2000. Across 16 jurisdictions, 997 sexual offenders were assessed; after a median of 41-month follow-up time period, the predictive accuracy of the three instruments was investigated. Based on these results, the Stable-2000 and the Acute-2000 were revised to their current versions (see Tables 1 and 2). Due to a relatively low predictive accuracy of the Stable-2000, the ratings of 3 items were adjusted. The risk area scores of the Stable-2000 became less important, and all items were added up to yield the final risk score. Additionally, the 3 items concerning *attitudes supportive of sexual offending* were dropped because they did not significantly predict sexual reoffending. With regard to the Acute-2000, the individual risk factor was dropped, and the researchers examined two different dimensions within the instrument. The first dimension was especially relevant for the prediction of sexual and violent recidivism and consisted of 4 items, while the second dimension represented a general

criminality factor which included all seven risk factors of the instrument.

Stable-2007

The current Stable-2007 version is an ARAI for sexual offenders comprising 13 stable dynamic items allocated to five risk domains. These domains and items are presented in Table 1.

The use of the Stable-2007 requires a thorough review of the files of the offender and an interview with him. Each risk factor has to be scored by considering whether or not this particular factor would play a risk-relevant role in the next 12 months assuming that the offender would have the opportunity to reoffend (i.e., that he is actually released and *on risk*). Each item is scored on a 3-point rating scale, with 0 for *no problem*, 1 for *some concern/slight problem*, and 2 for *present/definite concern*. Total scores are obtained by summing up all item ratings with higher scores indicating higher risk to recidivate. Total scores ranging from 0 to 26 are transformed into three risk categories: low, medium, and high.

Table 1 Domains and Items of Stable-2007

<i>Domains</i>	<i>Items</i>
Significant Social Influences	1. Significant social influences
	2. Capacity for relationship stability
	3. Emotional identification with children
Social Relationships	4. Hostility toward women
	5. General social rejection/loneliness
	6. Lack of concern for others
	7. Impulsive acts
General Self-Regulation	8. Poor cognitive problem-solving
	9. Negative emotionality/hostility
	10. Sex drive/preoccupation
Sexual Self-Regulation	11. Sex as coping
	12. Deviant sexual interests
Cooperation With Supervision	13. Cooperation with supervision

Additionally, these risk categories may be combined with risk categories of the Static-99 to obtain combined risk-need categories.

Measurement with Stable-2007 is very precise as shown by interrater reliability indices of .90 or higher (values of .75 and above typically are considered excellent according to conventional standards). Furthermore, the Stable-2007 is a strong predictor of sexual recidivism which is demonstrated by moderate to large effect sizes for the prediction of sexual recidivism in male adult sexual offenders in various studies from different countries and jurisdictions. Besides the Dynamic Supervision Project-based studies, there were two independent cross-validation studies from Austria which revealed significant effect sizes for the prediction of sexual recidivism with Area Under the Curve (AUC) values ranging between .67 and .71 for male sexual offenders released from the prison system as well as for forensic patients. Furthermore, the Stable-2007 has been shown to have incremental validity beyond static risk factors in different Canadian and Austrian samples.

Acute-2007

The current version of the Acute-2007 encompasses seven acute dynamic risk factors that are rated in four different categories from 0 for *no problem*, 1 for *maybe some problem*, 2 *yes, definite problem*, and to 3 for *intervene now*. The last category *intervene now* indicates situations in which the risk of reoffending may be sufficiently high to initiate immediate preventive interventions.

Table 2 lists the items of the Acute-2007. For the prediction of sexual recidivism, items 1–4 are summed; for the prediction of general recidivism, all items are summed for the final score rating. Both final scores aimed to predict recidivism within the next month and can be transformed into three risk categories: low, medium, and high. Additionally, these risk categories can be combined with the combined Static-99 and Stable-2007 risk-need categories to inform risk management decision-making processes and to further improve the prediction of recidivism. There has only been one comprehensive empirical investigation published about the reliability and validity of the Acute-2007, which is based on the Dynamic Supervision Project database from Hanson, Harris,

Table 2 The seven items of the Acute-2007

<i>Prediction of sexual recidivism</i>	<i>Prediction of general recidivism</i>
1. Victim access	1. Victim access
2. Hostility	2. Hostility
3. Sexual preoccupation	3. Sexual preoccupation
4. Rejection of supervision	4. Rejection of supervision
	5. Emotional collapse
	6. Change in social support
	7. Substance use

Terri-Lynne Scott, and Leslie Helmus in 2007. First, the findings support the predictive and incremental validity of acute risk factors. The results showed a high effect size for the sexual recidivism subscale and a moderate effect size for the general recidivism subscale in predicting recidivism for sexual offenders under community supervision. Second, a more in-depth analysis of the items included in the Acute-2007 indicated that the instrument is actually assessing dynamic, changeable risk-relevant propensities for offending.

STALKING

Stalking is the imposition of a pattern of repeated and unwanted intrusive acts by one person into the life of another, with the result that the victim (i.e., the target of the acts) experiences apprehension, distress, or fear. Stalking emerged as a concept in the English-speaking world during the 1990s. It first came to public attention because of the victimization of celebrities, then was recognized as a widespread social problem because of its links with domestic violence. Research has since shown that stalking affects a wide range of victims and is relatively common in industrialized societies. The entry reviews the epidemiology of stalking, the effects on victims, anti-stalking laws, and some proposed explanations for stalking behavior.

Description

Epidemiological studies of stalking suggest that approximately 17–30% of women and 4–12% of men in industrialized nations are victims of stalking at some point during their lifetime, with variation in estimates depending on the definition, sample, and method of inquiry. Victims are typically female (70–80%) and stalkers typically male (80–85%), with 10–20% of cases involving stalkers and victims of the same gender, the majority of these cases being male–male. Stalking, like any complex human activity, arises from a wide variety of intentions and influences. Meta-analytic reviews suggest that approximately 45% of stalking cases emerge following the dissolution of a romantic relationship, while the remainder are

perpetrated by people who were previously acquaintances of or strangers to the victims. In these cases, stalking is usually motivated by amorous intent or by a desire for revenge in retaliation for a perceived wrong. In a relatively small number of cases, stalking may occur as part of a pattern of sexually deviant behavior; in such cases, stalking may be a precursor to some form of sexual assault.

Definitions of stalking are necessarily broad and encompass a wide range of behavior that may cause distress to victims. Stalking most often involves relatively mundane if unwanted behaviors including repeated telephone calls or e-mail contacts; however, it can also involve terrifying and fortunately rare behaviors including sexual assault or severe physical violence. Between these extremes lies a range of harmful behaviors, including unwanted approaches (50–70% of cases), surveillance (30–40%), threats to injure or kill (at least 50%), property damage (approximately 20%), and nonlife-threatening physical violence (approximately 30%). As use of the Internet has become more pervasive, stalking online has also become common. Online stalking behavior, which has been labeled *cyberstalking*, can involve direct contact with the victim (e.g., e-mails, instant messaging, posts on social media), while others use the Internet to monitor the victim or cause harm (e.g., impersonating the victim, hacking their accounts, spreading malicious information). There is some debate about whether cyberstalking is fundamentally different from off-line stalking or merely another medium by which off-line stalkers can target their victims. Research suggests that most people who use cyberstalking tactics for prolonged periods also engage in off-line stalking; however, the literature in this area is still evolving and firm conclusions are not yet possible.

Effects on Victims

Stalking victimization is linked to significant negative psychosocial effects on victims, particularly if the stalking persists for longer than 2 weeks. This threshold is often used in research to define the presence of stalking behavior and to differentiate it from potentially less damaging forms of harassment. Early studies described a range of significant impacts of stalking, from symptoms of

traumatic stress to increased substance use, to damage to the victim's occupation and career. Subsequent epidemiological studies from multiple countries have quantified these impacts, showing that stalking victims experience higher rates of psychiatric morbidity than community members, which persists even after the stalking has ceased. It is also important to recognize the ripple effect of stalking on people associated with the victim (e.g., partners, other family members, coworkers). While there has been little specific investigation of the impacts on these secondary targets, it is known that they are often victims of physical violence by the stalker, and it would be reasonable to think that some of the psychological burden of stalking victimization also extends to them.

Anti-Stalking Legislation

Anti-stalking legislation was first introduced in California in 1990, and legislation with similar purpose was introduced in most English-speaking jurisdictions by 2000. Anti-stalking laws are less common in non-English-speaking jurisdictions, although a number of European and Asian countries introduced legislation during the 2000s and 2010s, using either the English terms or a local language variant to define the behavior. Some jurisdictions have opted for a summary and an indictable version of the offense, differentiated by the nature of the behaviors involved, while others have a single offense category. Anti-stalking laws have been criticized for being unnecessary, too broad, and for infringing on individual rights. In many jurisdictions, early anti-stalking legislation had to be reformed or rewritten due to problems with the original codification or application of the laws. Despite these problems, since 1990, there has been a steady increase in the criminalization of stalking behaviors around the world. While each jurisdiction defines stalking slightly differently, most anti-stalking laws require two or three critical elements to establish the offense:

- The *conduct element* is defined in one of two ways. Most laws provide a broad definition of stalking as a pattern of unwanted behavior. Some allow for police and court discretion in interpretation of what stalking might involve, while others provide a list of specific behaviors

that can constitute stalking. This latter approach is useful in that it may make application of the law easier or more consistent; however, it runs the risk of limiting the law if the list is not exhaustive. This has been dealt with in some jurisdictions by providing a catchall clause to prohibit behaviors that may constitute stalking but are not explicitly described.

- *Perpetrator intent* is usually dealt with either by requiring that it be proved that the perpetrator knew the likely impacts of his or her behavior and persisted regardless (an explicit knowledge or intent requirement), or requiring that it be shown that in behaving in the way that he or she did, the perpetrator was negligent or reckless as to the reasonably foreseeable impacts.
- *Effect on the victim* elements are part of many stalking laws and require that the victim must experience deleterious effects for stalking to be proven. In its most restrictive form, this requires that the victim actually feel fear as a result of the stalking. Less restrictive are requirements that there was some level of psychological harm or impediment to the victim's lifestyle. In some jurisdictions, there is no requirement that victim suffered negative effects and the proof of the offense is in the stalker's behavior rather than the victim's vulnerability to experiencing harm.

Explanations for Stalking

Stalking, like any complex human behavior, is the product of a range of psychological, social, and cultural factors. How these factors influence one another, why they produce stalking in one person but not another, and why stalking emerges in such a wide range of different contexts are all questions in need of answers. Existing explanations often focus on a single causal factor that is relevant to only some stalking cases (e.g., disturbed attachment), and there have been few attempts to integrate the body of stalking evidence into a multifactorial theory.

Psychopathology

Stalking has always been closely linked to psychopathology, and research shows that mental disorders are prevalent among stalkers, affecting at least half of stalkers who are in contact with

forensic systems. The most frequently reported diagnoses in forensic samples are personality, psychotic, depressive, and substance use disorders, although a wide range of other diagnoses are also reported. While mental disorder is common, it is rarely identified as the sole causative factor in stalking behavior. In a small number of cases, there is a clear causal relationship, usually when the stalker's delusional beliefs about the victim drive the behavior. In these cases, treating the delusion is the most effective way of ending the stalking. However, in most cases, treating symptoms is not an effective management strategy if used in isolation, indicating that other factors are also important in causing the behavior.

Disturbed Attachment

A number of authors have proposed that stalking is a consequence of disturbed attachment, specifically of preoccupied and/or anxious attachment. They have suggested that due to their attachment disturbance stalkers experience extreme negative emotions when confronted with relationship failure. The stalking is thought to be an attempt to either remove or devalue the victim, or to resume the relationship. In either case, the stalking acts to reduce negative emotional arousal. Research has shown that stalkers do have higher levels of disturbed attachment than nonstalkers, providing some support for this theory; however, insecure attachment is by no means ubiquitous among stalkers. Moreover, it would seem that not everyone who is insecurely attached stalks. As yet, the reasons why insecure attachment might produce stalking in some situations but not others remain unexamined.

Maladaptive Form of Courtship

Stalking in the context of relationship pursuit has been explained as a maladaptive extension of normal courtship behavior. Relational goal pursuit theory proposes that those who engage in persistent pursuit of relationships in the face of rejection tend to inflate the importance of relationship success and link it to their overall well-being and sense of self-worth. Therefore, when a relationship goal is thwarted, they are highly motivated to continue to pursue it. This

motivation is maintained by rumination about the goal and consequent negative emotional arousal. In this state, they rationalize (i.e., justify and minimize) their stalking behavior as necessary or simply fail to attend to its negative impacts on the victim. Relational goal pursuit is perhaps the best elaborated theory of stalking in an intimate relationship context, and evaluative research suggests that rumination and heightened negative emotion do play roles in persistent relationship pursuit.

Extension of Domestic Violence

Evidence indicates that between one third and two thirds of cases of postseparation stalking are preceded by domestic violence during the relationship. Moreover, domestic violence appears to be followed by postseparation stalking in between a quarter and half of cases. The close relationship between the two behaviors has meant that psychological theories of domestic violence that posit a role for disturbed personality and/or attachment and feminist theories that conceptualize domestic violence as an expression of patriarchal social structures and men's need for power and control over women have both been extended to stalking of former intimates. Findings from the large body of domestic violence research are also frequently generalized to extend to stalking. Yet, while they appear similar in expression and are clearly closely related in some cases, stalking and domestic violence do not seem to be coextensive. Further research is required on the conceptual and empirical links between these behaviors to best inform assessment, management, and prevention.

STALKING ASSESSMENT AND MANAGEMENT (SAM), GUIDELINES FOR

The Guidelines for SAM are a set of structured professional judgment guidelines for assessment and management of the risk of stalking—a pattern of targeted, repeated, and unwanted intrusive acts—which can cause serious physical or mental harm to victims. The diversity and the number of stalking cases make it difficult for police and other professionals to determine which cases require the greatest assistance to prevent negative outcomes and where to direct assistance to have the greatest effect. The SAM provides a structure for assessing stalking cases in a standardized way in order to help with case prioritization and management decisions. This entry provides an overview of the development, structure, and use of the SAM as well as a review of the empirical evidence related to its reliability and validity.

Development

The SAM was designed by a group of Canadian clinicians and academics with a strong history of research in and development of structured professional judgment risk assessment. Led by psychologist Stephen Hart, the same group has authored similar structured professional judgment risk assessment instruments for spousal assault and sexual offending as well as for general violence. The SAM was based in part on a systematic

review of the existing stalking research, consistent with recommendations for guidelines in the field of health care. The authors outlined many of the principles that underpin the SAM in a seminal 2002 article on challenges associated with assessing the risk of stalking. The SAM itself was published in 2008 after 3 years of field trials in Sweden and Canada. It was designed to assist professionals dealing with stalking to exercise their best judgment. It allows for immediate, systemic risk management of an ongoing stalking situation, focusing on risk factors associated with the stalking behaviors, the perpetrator's background and current presentation, and victim vulnerabilities that may exacerbate risk.

How to Use

The SAM is a 100-page manual available in English and Swedish, which guides the user through the process of assessing a stalking case, identifying relevant risk factors, developing risk scenarios and risk management strategies, and stating conclusory opinions. The SAM is intended for use by criminal justice, security, and mental health professionals working in a variety of contexts where complaints of stalking arise. It is intended for use in any case where there is a known or suspected history of stalking by a perpetrator over the age of 18 years.

The SAM must be completed separately for each perpetrator and victim, or group of related victims, being targeted. The risk factors included in the SAM are relevant to those who are known or suspected to have committed stalking. Risk judgments made using the SAM are specific to the current stalking situation and victim and cannot be generalized to apply to other forms of violence toward other people.

Users of the SAM are not required to complete any formal training; however, they should have expertise in individual assessment of stalkers or victims (through training or work-related experience) and expertise more generally in stalking. Users are not required to diagnose any form of mental disorder to use the SAM, making it accessible to nonmental health professionals. Users are required to complete approximately 8–16 hr of directed reading and supervised application of the SAM to be considered competent in its use.

Structure

Like all structured professional judgment instruments, the SAM guides the user to assess a number of risk factors associated with a particular risk outcome. Risk factors in the SAM are divided into three domains: Nature of Stalking includes 10 risk factors relating to the pattern of stalking behavior, Perpetrator Risk Factors are 10 factors reflecting the stalker's history and psychosocial adjustment, and Victim Vulnerability Factors are 10 factors relating to the victim's situation and psychosocial adjustment. Each risk factor is rated present (Y), possibly or partially present (?), or absent (N) during the current stalking episode and then separately for past presence outside the current stalking episode. Each risk factor is also rated for its relevance to the hypothesized causes of the person's stalking behavior. Risk factors identified as highly relevant are those that will be primary targets for interventions to reduce or prevent future stalking.

Once all risk factors are rated, SAM users are instructed to complete risk scenarios: Short narratives informed by their assessment of risk factors that describe the types of future stalking the perpetrator might commit. These scenarios typically canvas what might happen if the stalking continues its current course, if it reduces in intensity or severity, or if it worsens in intensity or severity; also included is a *twist* scenario where stalking behavior evolves in a new way, perhaps with different behaviors. The scenarios are used to guide the types of risk management that might be implemented with regard to monitoring of the case, treatment of the perpetrator, supervision/control of the perpetrator, and victim safety planning.

The final step in applying the SAM is to develop a number of conclusory opinions that communicate the main points of the risk assessment in a clear, simple manner that facilitates action. These judgments reflect the opinion of the user and address the following issues:

- Case Prioritization: A judgment about the degree of effort or intervention it will require to prevent the person from committing further stalking. Designed to assist with prioritization of resources where they are limited.
- Risk of Continued Stalking: The likelihood that the stalking of the victim will persist into the future, regardless of its nature or severity.
- Risk of Serious Physical Harm: A judgment about the severity of stalking the perpetrator might commit in future, with a focus on serious or life-threatening stalking-related violence.

Each of these judgments is rated as *low*, *moderate*, or *high*; these categories are associated with different levels of management. Any case judged to be at moderate or high risk or case prioritization should have more management resources focused on the case.

In addition to these judgments, the user makes judgments about the reasonableness of the victim's fear and whether immediate action is required to prevent harm. The former judgment attempts to capture the extent to which the victim's level of fear corresponds to the severity of the stalking, given the totality of the circumstances in the case. It is rated as *too low*, *appropriate*, or *too high* and helps to guide decisions about victim safety planning and counseling. A judgment about whether immediate action is required relates to the imminence of any future risk and is rated either *No* or *Emergency*, with the latter associated with imminent risk and issues surrounding the duty to warn or protect the victim, and the need for involuntary incapacitation of the perpetrator, or protective shelter for the victim.

Finally, users are instructed to recommend a date for review of the risk assessment. The SAM, like other structured professional judgment instruments, is designed to be valid for approximately 6 months from the date of assessment, with more frequent reassessment recommended if there are marked changes in the case (e.g., a dramatic escalation in the frequency of stalking contacts).

Reliability and Validity

The reliability of the three major SAM conclusory opinions (i.e., case prioritization, risk of continued stalking, and risk of serious physical harm) has been evaluated in five studies between 2009 and 2016, two of which also reported on concurrent and predictive validity. In 2009, a Swedish study evaluated the use of the SAM by police, concluding that police were able to rate all items, and

there was a clear positive relationship between the number of items present and overall risk judgments, providing a measure of the structural reliability of the instrument. Subsequent studies have reported mixed interrater reliability results. For Case Prioritization judgments derived using the SAM, agreement has ranged from slight to high (Interclass correlation, $ICC_{A,1} = .39$ to $.80$). Moderate agreement was observed across studies for both Risk of Continued Stalking ($ICC_{A,1} = .71$) and Serious Physical Harm ($ICC_{A,1} = .44$ to $.60$) judgments. The study reporting the highest levels of agreement used a sample of only six stalkers for interrater reliability analyses, while the largest such study ($N_{IRR} = 62$) found the lowest level of agreement for ratings. It should be noted that none of the studies published to date have investigated the reliability of ratings that distinguish between the risk factors' presence during the current stalking episode versus prior to that time (instead combining ratings into a lifetime score or rating only *current* presence).

The concurrent validity of SAM conclusory opinions was reported in 2011, through comparison with the results of other risk assessment instruments. SAM opinions correlated with a measure of psychopathy (the Psychopathy Checklist: Screening Version) between $.26$ and $.41$, while correlations with a measure of general violence risk (the Violence Risk Appraisal Guide) were approximately $.20$ (controlling for psychopathy). These small to moderate correlations were considered appropriate given that the risk instruments are attempting to assess somewhat different risk outcomes.

The predictive validity of the SAM has been reported once, in a 2016 U.S. study in which the SAM was prospectively rated in 89 (primarily ex-intimate) stalking cases involving convicted offenders. The Nature of Stalking and Perpetrator Risk Factors were scored in each case and used to make summary judgments (the information required to score Victim Vulnerability factors was not available). Each participant was followed up using police data, self-report, and treating clinician report over an average of 2.5 years to identify subsequent stalking or violent offending. Survival analyses showed that conclusory Case Prioritization opinions were not related to subsequent stalking or violent offending.

However, when the authors calculated a SAM score by assigning numerical values to risk factor

ratings in the Nature of Stalking and Perpetrator Background domains, perpetrators with higher total scores reoffended by stalking somewhat more quickly and more often than those with lower scores. The Nature of Stalking domain score alone similarly predicted stalking reoffending, although the Perpetrator score did not. There was no relationship between SAM scores and violent reoffending. Importantly, this study did not evaluate the Victim Vulnerability factors as the authors did not have access to victim information, which may have impacted the predictive validity of the instrument. The authors concluded that the study provided mixed support for the predictive validity of the SAM in clinical forensic settings as a risk assessment instrument for stalking.

STALKING RISK PROFILE (SRP)

The SRP is a structured professional judgment instrument that guides risk assessment in stalking situations. Stalking—a pattern of targeted, repeated, and unwanted intrusive acts—can cause significant harm to victims, particularly when it is persistent or involves physical violence. The SRP provides a structure for assessing the likelihood of these outcomes by evaluating the presence of risk factors linked to each. Judgments made using the SRP can help professionals to more effectively allocate resources to manage stalking situations. This entry describes the development of the SRP, outlines its use, describes its structure, and reviews the empirical evidence for the reliability and validity of the SRP.

Development of the SRP

The SRP was developed by a team of Australian and English clinician academics, drawing on their research, which began in the early 1990s, into the understanding and treatment of stalkers and their victims. The content of the SRP was also heavily influenced by the authors' clinical work with stalkers and victims in forensic, mental health, and policing settings and broader research into violence risk assessment.

The SRP was first presented in a 2006 article as a set of brief guidelines designed to help professionals consider risk factors that may be relevant in a specific stalking case. The guidelines emphasized that when assessing stalking risks, it was important to consider both the nature of the prior relationship between the stalker and victim and the stalker's apparent motivation. Drawing on the nascent stalking risk assessment literature and the authors' clinical practice, the article highlighted the importance of understanding the stalker's history of similar behavior toward the same victim or others, the nature and pattern of stalking behaviors in the current stalking episode, and the role of clinical factors, including stalker psychopathology and personality. Situational factors and victim

vulnerabilities that may exacerbate risk of continued stalking, physical violence toward the victim, or other negative outcomes were also canvassed. These brief guidelines were elaborated on and developed into a full, structured professional judgment instrument that was published in 2009.

Using the SRP

The SRP is a 100-page manual available in English, Dutch, and German. It guides the user through the process of assessing risk factors associated with different types of stalking risk and developing management plans for stalkers. It includes a specific section highlighting additional areas for consideration when assessing risks to stalking victims who are public figures (e.g., politicians or celebrities).

The SRP is intended for use with individuals aged 18 years and older where there is evidence of current or past stalking behavior. The SRP is specific to a particular stalking case, with a separate risk assessment completed for each unique stalker–victim pair. Mental health professionals are the primary intended users, although professionals including law enforcement are able to apply the SRP with formal training and diagnostic support from a mental health clinician. Users are required to be familiar with conducting interview-based assessments and with their local anti-stalking legislation. A 2-day training workshop is required for those unfamiliar with structured professional judgment risk assessment or stalking.

Structure of the SRP

The SRP differs from other structured professional judgment tools in that the risk factors assessed in a specific case depend on both the risk outcome being assessed and the stalker's underlying motivation. This structure was based on research indicating that risk factors were differentially related to stalking outcomes. For example, threats are associated with physical violence in a stalking episode but are unrelated to stalking duration, while psychotic symptoms have the opposite relationship, being unrelated to stalking violence but strongly predictive of duration. The authors also observed that risk factors that were highly relevant in some stalking situations were simply irrelevant to others. For example, where

the stalker is a rejected former intimate, sharing children or property with the victim is a risk factor for continued stalking. This risk factor simply does not apply when the stalker and victim had no prior relationship. The SRP therefore uses the type of risk and the apparent motivation of the stalker to cluster risk factors into distinct sets, each of which results in a separate risk judgment.

Domains of Stalking Risk

The SRP can assess six areas of stalking-related risk. Two relate to the potential for future stalking behavior, one to the potential for physical violence toward the current victim, one to the stalker's level of psychosocial need, and two are specific to public figure stalking situations. Each is defined further below. Administration of the SRP will usually result in risk judgments in three domains, five if victim is a public figure.

- *Persistence* is the likelihood that a person will continue to stalk this victim. Persistence is assessed when there is evidence that the stalker has intruded upon this victim within the previous 6 months.
- *Violence* is the likelihood that a person who is currently stalking will engage in physical violence toward the stalking victim or people associated with the victim. Violence is specifically defined as physical contact intended to coerce or harm.
- *Recurrence* is the likelihood that a person who has stopped stalking will resume. The Recurrence domain is scored only if the stalker has not intruded upon the victim for a period of 6 months, despite being at liberty to do so. Two Recurrence judgments are made: one regarding future stalking of the same victim as in the previous episode (Recurrence_{same}) and the other relating to future stalking of a different victim (Recurrence_{different}).
- *Psychosocial Damage to the Stalker* is the likelihood that the stalker will experience significant psychological and social harm due to his or her behavior and situation. High levels of psychosocial need increase risk in other domains and may present challenges for engaging the stalker in offense-related treatment.
- *Escalation* is the likelihood that stalking of a public figure will escalate from communication to attempting to approach the victim. This domain helps agencies responsible for public figure protection to allocate resources to cases posing the greatest physical threat.
- *Disruption* is the likelihood that stalking of a public figure will involve significant disruption, distress, and/or embarrassment. This domain helps security agencies identify cases that may involve significant disruption to the target's activities and so require management, even if other domains of risk are low.

Stalker Motivational Types

Assessment of the stalker's motivation is integral to the structure of the SRP as it partially determines the risk factors that are assessed. The SRP classifies motivations using the typology developed by leading stalking researchers Paul Mullen, Michele Pathé, and Rosemary Purcell. The prior stalker–victim relationship, the stalker's apparent initial motivation for seeking unwelcome contact with the victim, and the presence and nature of psychopathology are used to classify a stalking episode into one of five types.

- *Rejected* stalkers begin after the breakdown of a close relationship. Former sexual intimates belong to this type, but it may also include others in close relationships such as family members or friends. Rejected stalkers are motivated by a desire for reconciliation, revenge, or both and are not typically afflicted by severe mental illness.
- *Resentful* stalkers target strangers or acquaintances who they believe have wronged them in some way. Resentful stalkers seek revenge against their victims as a way to regain a sense of power and control and frequently present with paranoid personality traits or frank psychoses that contribute to their sense of injustice.
- *Intimacy Seekers* stalk acquaintances or strangers with whom they falsely believe they have a loving relationship, often due to a severe mental illness. The stalking is often driven by a (potentially delusional) conviction that either the victim loves them in return or inevitably will love them if they only persist.

- *Incompetent Suitors* are seeking to establish friendships or dating relationships with strangers or acquaintances. Motivated by loneliness or lust, their approaches are unsophisticated and intrusive. Incompetent Suitors are not necessarily affected by mental illness, but they often exhibit impaired social skills or interpersonal deficits.
- *Predatory* stalkers target strangers or acquaintances to obtain sexual gratification, which is often deviant in nature. Predatory stalkers do not usually suffer from serious mental illness, although diagnoses of paraphilia, substance abuse, personality disorder, and depression are common.

Judgments about motivational type for the SRP are facilitated using a decision tree. Once the user has determined the type of stalker, the choice of risk factors to assess in each risk domain is restricted to those relevant to that type.

Risk Factors and Risk Judgments

Depending on type of stalker and the domains of risk to be assessed, administration of the SRP involves rating between 32 and 40 risk factors. Each is rated as present (Y), possibly or partially present (?), or absent (N). When all risk factors in a domain have been rated, the assessor makes a risk judgment of *low*, *moderate*, or *high* risk for that domain. Risk judgments are a clinical decision made by the assessor but are guided by the number and nature of risk factors that are present in that domain. Like other structured professional judgment instruments, the risk judgment categories are tied to the anticipated level of resourcing and intervention required to prevent an adverse outcome. Risk judgments are valid for approximately 6 months from the time of assessment and, with the exception of Recurrence_{different} judgments, are specific to risks to the victim of the current stalking episode.

Reliability and Validity of the SRP

The SRP has been evaluated in a single study of the English manual conducted by the authors of the instrument. The SRP was administered in 256 Australian stalking cases (93% male), with law enforcement charges for stalking and related

offenses used to measure recidivism over an average follow-up time of 4.3 years. Interrater reliability of decisions about stalker type was excellent ($\kappa = .98$). The interrater reliability of risk judgments was moderate to substantial, with intraclass correlations (one-way, random effects model, single ratings, absolute agreement method) ranging from .70 for Recurrence_{same} judgments to .90 for Persistence judgments. Risk judgments for Persistence and Recurrence were able to discriminate between stalkers who did and did not engage in further stalking. There was a 66–68% probability that a randomly selected reoffender would have a higher risk judgment on the SRP than a randomly selected nonreoffender. Those judged to present a high risk of future stalking of the same victim (either Persistence or Recurrence_{same}) were more than 6 times as likely to reoffend against the victim as those judged to present a low risk. Those judged to present a high risk of Recurrence_{different} were almost 4 times as likely to reoffend by stalking a new victim as those judged low risk. The validity of violence risk judgments was not reported in this study due to low rates of violent reoffending. The authors concluded that the results indicated that the SRP shows promise in clinical forensic settings as an effective risk assessment tool for stalking.

STANFORD PRISON EXPERIMENT

The 1971 Stanford Prison Experiment (SPE) is one of the best known psychology studies of all time, both for its dramatic demonstration that ordinary people have the capacity to impose serious harm on their fellows and also for its simple and striking explanation of this phenomenon: Human beings cannot help but succumb to the demands associated with the roles into which they are thrust.

The study is not only a staple in every introductory psychology textbook, it has transcended disciplinary boundaries and is regularly cited across the humanities and social sciences—most famously, perhaps, in Christopher Browning’s acclaimed historical study of a Nazi killing squad *Ordinary Men*. But more than that, the SPE has permeated from the academic world into popular culture. In particular, it has been the basis for several feature films.

Over the decades since the study was conducted, it has been widely cited as evidence of the impact of situation on behavior and of the way in which extreme situations can engender extreme behavior. But while contemporary scholarship generally accepts the phenomena that the SPE reveals, the lead researcher Philip Zimbardo’s theoretical account has much less support and is very much out of step with decades of research in social psychology.

Background

In the SPE, Zimbardo and his colleagues explored whether an authority figure needs to be present in order for people to exhibit brutality toward

others. More particularly, they asked whether, if you assign people to a role that is associated with clear role expectations to be brutal, they will conform even without anyone instructing them how to act.

Zimbardo and his team were interested in addressing this general question in one particular social context: the prison. This was because they were struck by the wave of prison unrest that had swept across the United States in the 1960s, culminating in the 1971 Attica riot in which 34 inmates died. They were particularly struck by the mounting evidence of brutality on the part of prison guards, well expressed in a 1972 *Time* article about Attica that concluded that the guards had “anaesthetized their humanity” (p. 22). Thus, the SPE was designed to address questions that were of profound importance not just for academics but for society at large.

The Study

The SPE started in 1971 with Zimbardo and his colleagues recruiting “mature, emotionally stable, normal, intelligent” young men to take part in a “psychological study of prison life.” Once 24 participants who appeared to fit this description had been identified, they were randomly assigned to either the role of a prison guard or a prisoner. With the cooperation of the local police force in Palo Alto, the prisoners were picked up in a mock raid (but in real police cars) and taken to the basement of the Psychology Department at Stanford University, which had been transformed into a prisonlike environment. Zimbardo placed himself in the role of prison superintendent, and a student assistant, David Jaffe (who had previously conducted a class exercise with a similar design that had piqued Zimbardo’s interest), took on the role of prison warden. A former convict, Carlo Prescott, provided advice on how to create a setting that would simulate imprisonment, including the psychology of such.

The guards were given a uniform consisting of khaki shirts, trousers, and reflective sunglasses. They were also provided with repressive tools: a whistle and a night stick. By contrast, the prisoners were systematically humiliated and degraded from the moment of their arrival. They were stripped naked, sprayed with a *delousing agent*, given a number by which they were to be referred (rather than by name), and forced to wear a short

smock without underwear, rubber sandals, a cap made from a nylon stocking, and chains on one ankle. They were then locked up in three-man cells measuring six by nine ft. There was also a windowless closet—the *Hole*—which could be used to place prisoners in solitary confinement punishment.

Critical to the logic of the study by Haney, Banks, and Zimbardo, in 1973, was that beyond the guards being told that they had to “maintain the reasonable degree of order within the prison necessary for its normal functioning” (p. 7), Zimbardo asserts that the participants were not trained in how to perform their randomly assigned role.

Findings

At the start of the study, the prisoners felt aggrieved at their circumstances and the way they were treated. They became insubordinate. They planned rebellion. The occupants of two cells removed their caps and prison numbers and barricaded themselves into their cells. By the end of the first day, the prisoners were in the ascendant and the guards felt confused, disempowered, and resentful.

At this point Zimbardo intervened. He took out one of the rebel prisoners, No. 8612, and sought to recruit him as an informer. The rebel also left with the impression that the prisoners no longer had the right to leave the study. As Zimbardo recounted in 2007, the rebel returned to his cell screaming “you can’t get out of here”—although it remains unclear whether Zimbardo himself had said this explicitly or whether it was a misimpression that Zimbardo did not correct. Whatever the case, the impact on the prisoners and that on the balance of power in the prison was dramatic. At this point, the guards too decided to suppress rebellion. They broke into the barricaded cells, stripped the protestors naked, and put the ringleader into the Hole.

From this point, the guards became more repressive. They subjected the prisoners to long roll calls. Anyone who objected was singled out for humiliation. Prisoners were forced to perform arduous physical tasks (e.g., push-ups with a guard’s foot on their back), needlessly foul menial chores (e.g., cleaning toilet bowls with their hands), and sexually humiliating acts (e.g., playing homoerotic games of leapfrog). As this happened,

the prisoners themselves became increasingly passive and some began to show signs of psychological disturbance.

Overall, the situation had become highly toxic. As Zimbardo recounted it in 2007, this was something to which he himself had become blind. It was only when a visitor to the study, Christina Maslach (Zimbardo’s future wife), expressed shock at the depravity into which the guards had sunk that Zimbardo was motivated to bring the study to a premature close. Thus, even though it was scheduled to last for 2 weeks, the study concluded on Day 6. Reporting to Congressional Hearings shortly afterward, Zimbardo, in 1971, explained:

At the end of only six days we had to close down our mock prison because what we saw was frightening . . . human values were suspended, self-concepts were challenged, and the ugliest, most base, pathological side of human nature surfaced. (p. 154)

Zimbardo’s Explanation

Zimbardo’s explanation of his findings takes the form of strong situationism. He assumes that the behavior of participants in the SPE was entirely determined by features of the context such that anyone who had been placed in that context would have behaved similarly. More specifically, he argues that participants could not help but take on the roles to which they had been assigned (i.e., as prisoner or guard) and act in terms of the requirements associated with those roles. When it comes to acts of the guard’s aggression, Haney and colleagues, in 1973, claim that these were “emitted simply as a ‘natural’ consequence of being in the uniform of a the ‘guard’ and asserting the power inherent in that role” (p. 62).

In 2007, Zimbardo applied a similar analysis in an attempt to elucidate the psychological underpinnings of a range of contemporary atrocities—notably the 9/11 attacks carried out by members of Al-Qaeda and the abuse of prisoners perpetrated by U.S. military personnel at Abu Ghraib prison in Iraq. Referring to the SPE and Abu Ghraib, he argues that both exhibit similar psychological dynamics: “bad systems [prisons], create bad situations [brutal regimes], create bad apples [brutal guards], create bad behaviour [abuse of prisoners]” (p. 445).

Criticisms and Alternatives

One year after the abuse at Abu Ghraib had come to light, Zimbardo's expertise on the subject of prison abuse led to him being asked to act as an expert witness for the defense of Ivan "Chip" Frederick, who was one of the military policemen implicated in the abuse at Abu Ghraib. In line with his situationist account of findings in the SPE, Zimbardo argued that responsibility for creating a toxic situation lay higher up the command chain and that Frederick was just a victim of that situation. The prosecutors, Charles Graveline and Clemens in 2010, disagreed, arguing: "to say that bad action becomes inevitable negates the responsibility, free will, conscience, and character of the person" (p. 179). Faced with the evidence, the judge sided with Graveline. Frederick was found guilty, sentenced to 8 years' detention, and given a dishonorable discharge.

Yet, aside from the moral and political issues that were pertinent to the Frederick case, scholars have proffered three main reasons to doubt both Zimbardo's account of what happened in the SPE and his explanation of it. First, the role explanation depends on accepting that participants acted of their own accord with no external shaping or direction. As noted earlier, to support his theoretical analysis, Zimbardo claimed that his participants had received no prior training in how to act. Yet the transcript of his briefing of the guards before the study in 2007 began throws this claim into question. He told the guards:

You can create in the prisoners feelings of boredom, a sense of fear to some degree, you can create a notion of arbitrariness that their life is totally controlled by us, by the system, you, me—and they'll have no privacy. They'll have no freedom of action, they can do nothing, say nothing that we don't permit. We're going to take away their individuality in various ways. In general what all this leads to is a sense of powerlessness. (p. 55)

Thus, even if Zimbardo did not describe the precise forms of action that the guards should undertake, he gave them an indication of the general ways in which the prisoners should be treated. More subtly, through his use of *we* and *they*, he positioned himself as integral to the guard group

(rather than as a neutral experimenter). More particularly, Zimbardo positioned himself as leader of the guard group, and if, as the leader, he advocated harsh measures, then, as S. Alexander Haslam, Stephen D. Reicher, and Michale J. Platow assert, his study should be seen as an investigation of leadership and followership not simply as a study of role conformity.

Second, even with such leadership, the study is rife with resistance from start to end. The prisoners did not all accept their assigned roles, and dissent was widespread among the guards. In the video *Quiet Rage*, Zimbardo acknowledges that the guards split into three factions: those who sided with the prisoners, those who were firm but fair, and those who were abusive. Indeed, there is only one unambiguous instance of an abusive guard, an individual who came to be known as *John Wayne* for his aggressive swagger. Accordingly, it seems implausible to argue that conformity is inevitable and that individual differences (whatever their nature or basis) are not important.

Third, where there was abuse, it did not reflect passive compliance with role requirements on the part of the guards. Rather, they were creative in finding new ways of targeting the prisoners. This is exemplified in an exchange between *John Wayne* and one of those he had tormented, shown in *Quiet Rage*. At one point, the guard asks his victim what he would have done had he been in his position. The prisoner replies, "I don't know. But I don't think I would have been so inventive. I don't think I would have applied as much imagination to what I was doing . . . If I had been a guard I don't think it would have been such a masterpiece."

In sum, scholars have argued that Zimbardo's situationist explanation fails to account for the patterning of behavior that was produced within the SPE. Close inspection suggests that guard abuse was legitimated and guided by Zimbardo's authority but that the guards had agency both in choosing to follow his guidance and in deciding how to apply it. That is, the abusive guards were *engaged followers* who did not conform passively like zombies, but who behaved as they did because they actively identified with their role and with Zimbardo's leadership.

This *engaged followership* analysis was lent further support by the 2006 BBC Prison Study. This

study revisited the paradigm and issues raised by the SPE by dividing men into groups of prisoners and guards within a simulated prison environment. However, it provided a more systematic investigation of the conditions under which participants identify or do not identify with their roles and showed that it was on this basis that they accepted role demands or else resisted them.

Conclusion

The SPE provides a powerful illustration of the power of situations to transform behavior and of the ways in which ordinary people can be led to behave in abusive ways. However, the analysis of the study that Zimbardo provided in 2007 overstates the generality and automaticity of this phenomenon—failing to pay sufficient attention to resistance to situational demands, even within the SPE itself. Intellectually, more attention needs to be paid to the dynamics that determine whether people identify with their roles and hence are motivated to creatively enact them. Politically and morally, it is also important to acknowledge that abusers do make choices and hence are accountable for their actions.

STATE PRISONS

State prisons refer to correctional facilities that are operated by a state government rather than federal government. According to the Treatment Advocacy Center, a nonprofit organization that advocates for the effective treatment of severe mental illness, approximately 234,200 individuals with severe mental illness were incarcerated in state prisons across the United States in 2014. This number comprised 15% of the total inmates located in U.S. state prisons that year. This reflected a 5% increase over 10 years, based on statistics collected by the Department of Justice in 2004. Inmate rights to health care, including mental health care, are defined by the U.S. Constitution (Eighth Amendment prohibition against cruel and unusual punishment) and in several landmark U.S. District and Supreme Court cases, including decisions in *Estelle v. Gamble* (1976) and *Ruiz v. Estelle* (1980). An examination of the background for these court cases reveals that mental health care lagged behind medical care in terms of importance and appropriation of resources (i.e., financial, facilities to provide care, use of evidence-based practices, and employment of appropriately educated and trained mental health-care providers) for many years. However, correctional administrators are facing shifting priorities, as the number of inmates with serious mental illness has increased steadily over time and more resources have been devoted to improving the quality of

mental health-care services in state correctional systems. The increased need to treat mental illness in correctional facilities has resulted in the revision and broadening of standards from correctional health-care accreditation bodies, such as the National Commission on Correctional Health Care and the American Correctional Association. This entry on state prison systems offers a review of mental health programs, outlining best practices as well as challenges inherent in offering these services in correctional environments.

Entry or Intake Process

The provision of health-care services, which includes mental health care and psychiatric care, begins with the intake process. Newly convicted and sentenced inmates generally enter the state prison system through a designated intake or processing facility. The specialized missions of these facilities include evaluating the health and mental health-care needs of newly arrived individuals, in addition to specific administrative procedures designed to evaluate the inmate's security and custody level. The resulting disposition is utilized to identify the inmate's needs and to determine facility assignment and management plans (including treatment).

Mental health intake processes vary across systems, but general goals include identification of risk of suicide or harm to others and significant mental health issues that will require ongoing treatment services such as psychotropic medication management and counseling services. Intake mental health professionals focus on diagnostic assessment processes and ensure that accurate diagnostic determinations are made for each inmate; psychological testing and procurement of community mental health records can be very beneficial in the assessment effort. In many systems, the collection of information relevant to community reentry also begins during the intake process.

Programming and Services for Special Populations

As noted, state prison systems have been expected to adapt to managing an inmate population with more serious mental health issues than previously experienced. Inmates identified with severe mental

illnesses and those with other unique needs warrant specific attention within correctional settings. Inmates garnering specialized treatment and management services include those diagnosed with serious mental health issues, inmates who have developmental disabilities or neurocognitive disorders, frail and older adult inmates, juveniles convicted as adults, inmates with physical disabilities, and those who identify as transgendered. Female inmates also present with unique challenges for state correctional systems, as many incarcerated women have significant trauma histories that make adjustment to correctional settings difficult.

Inmates diagnosed with serious mental health issues tend to serve longer sentences than those without significant mental health issues and often experience greater struggles attempting to manage behavioral expectations while incarcerated. It is known that stress often precipitates mental health crises, and stress levels in correctional settings can be very high. In addition, inmates presenting with unique needs may be targeted by other inmates for various reasons. Mental health staffing ratios for facilities are typically designed to meet the needs of the varied inmate population, and specialized training is generally offered to the mental health staff who work in correctional facilities. While many excellent evidence-based treatment programs have been developed, there are only a few developed specifically for correctional populations given the challenges of conducting the needed research in correctional settings. Treatment staff should be supported in their use of the programs designed for inmates, as well as in efforts to adapt other evidence-based programs for use in correctional settings. Some state systems do participate in research efforts, generally through university-based psychology graduate programs, to design treatment programs specific to this inmate population.

State prison systems generally offer a broad range of treatment services, including mental health counseling, psychotropic medication management, and substance abuse and sex offender treatment. Various treatment modalities are utilized, including individual and group treatment opportunities. Inmates often prefer individual treatment for many reasons. However, group treatment offers several benefits such as the ability to practice skill building with peers, to develop a greater sense of empathy, and to understand the

benefits of positive social support by developing more successful interpersonal skills.

Crisis assessment and intervention services are also essential components for correctional mental health programs, as suicide risk is higher among correctional populations compared to the community. While there is some overlap in risk factors for self-harm behaviors between correctional and community populations, there are also unique factors that must be considered when working with an incarcerated population. Such factors are related to environmental stressors, separation from family, and legal stressors, to name only a few.

Inmates isolated from the general prison population in restrictive housing units, or segregation, present a host of needs for correctional mental health care. Isolated housing can bring about depressive and anxious functioning and sleep problems, contribute to physical decompensation, heighten suicidal ideations, and lead to the exacerbation of symptoms for those struggling with mental illness. The mental health professional's role for this subset of the prison population includes monitoring and assessment, treatment planning and implementation, behavior management, and consultation and recommendations regarding placement. In addition, mental health staff assist in the implementation of programming aimed at assisting the inmate to effectively maintain in or transition out of segregated housing.

Many state systems have specialized mental health units that offer intensive treatment services for inmates whose illness acuity does not allow them to safely reside in general population settings. Some states operate licensed mental health inpatient facilities, whereas others operate units that follow correctional accreditation standards for intensive treatment units. These units typically utilize a clinical treatment team model led by a psychiatrist, have high treatment staff to inmate ratios, and offer structured programming on a daily basis. Correctional staff are often specially trained to manage such units, and ratios of correctional staff to inmates in these units are also higher than in general population settings. Some state systems allow the use of involuntary medication processes, with procedures typically based on the U.S. Supreme Court decision in the case of *Washington v. Harper* (1990). Other states do not offer intensive treatment units for a variety of reasons, and these states generally work with state or

private psychiatric hospitals to transfer inmates to secure units for treatment.

Multidisciplinary Teams

The most successful mental health programs in state correctional systems make use of a multidisciplinary team model, and such an approach has become more important as the acuity of mental illness has increased. Multidisciplinary teams generally include members from mental health, medical, nursing, case management, security, and administration. All team members are expected to maintain confidentiality regarding inmate health and mental health information, and the presence of security and administrative representatives is essential given the reality of carrying out treatment services in security-focused environments. Inmates who present unique management challenges require a team approach for successful management and the safety of all personnel involved in the care of the inmate.

A particular benefit of the multidisciplinary team is highlighted when the need arises for a specialized behavioral management plan. There is a small but particularly challenging group of inmates who present not only with significant mental health issues but also with special security challenges given their potential to harm others and/or destroy property. A behavioral management plan can be implemented to set behavioral goals that allow the inmate to regain lost facility privileges or become eligible for new privileges. Some aspects of the plan may require special permissions that only administrative and/or security personnel can provide. Well-planned and consistently implemented behavioral management plans can improve the safety and security of an institution and provide an opportunity for an inmate to function more successfully.

Many inmates have significant medical and substance abuse comorbidities in addition to serious mental health issues. Clinical meetings between medical and mental health services are essential to ensure that inmates receive appropriate, effective, and efficient treatments and that health-care providers are able to share information seamlessly. In addition, identifying the role substance use plays in the mental and physical functioning of the inmate is vital, and communication of those findings among medical and mental health providers is also important.

Discharge and Reentry Services

More than 90% of inmates in state prison systems will be released back into the community at some point. This reality stresses the importance of preparing inmates for return to their community, as reducing risk of recidivism is a goal for all state correctional systems. Particular challenges for inmates with serious mental health issues include ensuring a seamless transition to appropriate treatment services in the community, including mental health care and psychiatric care, along with substance abuse and sex offender treatment services. Additional challenges include securing employment and income (including disability benefits), health insurance, housing, and transportation.

Inmates who release on parole may benefit from working with specially trained parole officers who are prepared for the reentry challenges offered by this group of inmates. Inmates who release *off paper* and do not have parole requirements may have a particularly difficult transition, especially if there are no family members or friends willing to provide assistance. Discharge and reentry planning efforts may start as early as 18 months before release for those inmates expected to have the greatest challenges in the transition process, and programming such as Life Skills and ongoing substance abuse treatment services can be particularly beneficial.

Ethical Issues

Attention to ethical practice should be at the forefront for any health-care professional, and practice within correctional settings brings additional ethical issues to consider. An exhaustive review of this topic is beyond the scope of this entry, but a few key points are noted here. Confidentiality has different parameters in correctional versus noncorrectional practice settings. Safety and security of the institution is paramount, and most state systems outline additional mandatory reporting issues, such as planned escapes and knowledge of drug use and sales in the facility. Some states also have specific statutes that require reporting knowledge of crimes beyond child and vulnerable adult abuse, and correctional mental health professionals are expected to be familiar with these statutes.

Therapeutic boundaries are also exceptionally important in correctional settings, as mental health professionals, as empathic and caring professionals, may be targeted by inmates who want to curry favor or obtain contraband items. As a result, the mental health professional electing to work in the correctional setting must demonstrate the ability to balance the treatment needs of the inmate while still adhering to the safety and security of the facility, as well as the specific statute requirements of the state. Providing clinical services as part of a larger treatment team in correctional settings can provide the support mental health-care providers need to ensure adherence to professional ethics and facility guidelines.

STATIC-2002 AND STATIC-2002R

The Static-2002 and its revised version, the Static-2002R, are risk assessment tools that are used to predict sexual recidivism. Both versions were created by Karl Hanson and David Thornton as

improvements on the Static-99 and the Static-99R risk assessment tools. This entry begins by providing some background information and then discusses the purposes, evaluation, and use of the Static-2002 and the Static-2002R.

Background

In the field of risk assessment, research has consistently demonstrated that risk assessments that are structured have increased accuracy when compared to unstructured professional opinion or clinical judgment. This being said, within the field, there is a lack of consensus as to how known predictive factors should be structured. One method for structuring risk factors in assessment is known as the *actuarial method*. Actuarial risk tools are regularly used in forensic psychology in both applied and research settings. Such tools provide a clinician or researcher with an explicit algorithm for combining known risk factors that have been shown to be predictive of recidivism. Such tools provide an empirically validated method of combining risk items into an overall score. The overall score derived provides users with a way to meaningfully compare the person currently assessed with known samples of offenders.

As noted earlier, Hanson and Thornton created Static-2002 with the primary goal of improving the Static-99. They designed the Static-2002 to be similar to the Static-99 in that it was intended to be a brief actuarial measure that was predictive of sexual recidivism while making use of information common to many forensic assessors. Another goal was to address the perceived weaknesses of the Static-99. The Static-99 was created by merging two previously existing scales (Rapid Risk Assessment for Sexual Offense Recidivism and Structured Anchored Clinical Judgment), which led to two separate sets of item definitions being merged into the Static-99. In designing the Static-2002, Hanson and Thornton selected the definitions with the strongest support in pilot studies and structured the items into subscales for the purpose of interpretation. With these changes, it was also hoped that the Static-2002 would be more accurate than the Static-99 at predicting sexual and violent recidivism.

Following the publication of the Static-99 and the Static-2002, given the data that criminal

behavior generally declines with age, it was deemed to be empirically appropriate to adjust the Static-99 and the Static-2002 to statistically factor age of release into these assessment tools. Sequentially, there was a revision of both the Static-99 and the Static-2002, and these tools became known as the *Static-99R* and the *Static-2002R*.

The Static-2002R is a 14-item actuarial measure designed to predict both sexual and violent recidivism in sexual offenders. The items of the Static-2002R are identical to the Static-2002 with the exception of updated age weights. When compared to the Static-99, the Static-2002R added or altered some items, organized items into meaningful subscales with the goal of assisting interpretation, and is believed to have more standardization in coding rules. The Static-2002R items are grouped into five main subscales: Age at Release, Persistence of Sex Offending, Sexual Deviance, Relationship to Victims, and General Criminality. The total score of the Static-2002R ranges from -2 to 13. The total score of the Static-2002R can be used to place offenders in one of five risk categories: very low (-2 to -1), below average (0-1), average (2-4), above average (5-6), and well above average (7+). The items of the Static-2002R are as follows: (1) age at release, (2) prior sentencing occasions for sexual offences, (3) any juvenile arrest for a sexual offence and convicted as an adult for a separate sexual offence, (4) rate of sexual offending, (5) any sentencing occasion for noncontact sex offences, (6) any male victim, (7) young, unrelated victims, (8) any unrelated victims, (9) any stranger victim, (10) any prior involvement with the criminal justice system, (11) prior sentencing occasions for anything, (12) any community supervision violation, (13) years free prior to index sex offence, and (14) any prior nonsexual violence sentencing occasion.

Purpose and Evaluation of the Static-2002 and the Static-2002R

Most predictive research on the Static-2002 and the Static-2002R has focused on the ability of these measures to distinguish offenders on their risk of recidivism. Typically, predictive accuracy is presented statistically using correlation coefficients, areas under receiver operating characteristics

curves (AUC), or standardized mean differences (Cohen's d). Correlation coefficients quantify the statistical strength and direction of the relationship between two or more values. A receiver operating characteristic curve is a graphical curve created by plotting the true positive rate (sensitivity) against the false-positive rate ($1 - \text{specificity}$) and sequentially evaluating the ability of an instrument to discriminate a binary dependent variable (i.e., in this case recidivism). AUC values range from 0 to 1. A score of 1 means that the test in question is perfect in its predictive and/or diagnostic abilities. An AUC value of 0.5 means that a predictive or diagnostic tool worked in a fashion that was equivalent to chance. Cohen's d measures the difference between two means divided by a standard deviation for the data. All of these statistics describe the extent to which the recidivists are different from the nonrecidivists; however, these statistics do not provide absolute recidivism rates. It is important to note that absolute recidivism rates (i.e., the percentage of individuals who reoffend) differ in the literature from sample to sample and that relative risk measures (e.g., risk ratios or percentiles, which compare the level of risk of one offender, to that of other offenders) are considerably more stable.

Use of the Static-2002 and the Static-2002R

The Static-2002 and the Static-2002R can be used by a wide range of evaluators in terms of educational or training background. The instrument developers recommend that users receive specific training in the Static-2002R and related measures (i.e., the Static-99 and STABLE 2007) prior to clinical use.

The Static-2002 and the Static-2002R were designed to be used with male sexual offenders who have been convicted of at least one sexual offence after their 18th birthday. The Static-2002 and the Static-2002R should not be used with offenders who have abstained from violent offending while in the community for a period of 8 years or more since release from their most recent sexual offence. The measures are not recommended when the only sexual infraction involved consenting sexual activity with a similar-age peer. The measures should not be used for offenders whose only sexual offence is one of the following:

consenting sex with adults in public places; child pornography offences (unless the offender was involved in manufacturing the child pornography); indecent behavior with no sexual motive; failing to inform a sexual partner of HIV positive status; prostitution, pimping, or pandering (including profiting from child prostitution); bigamy; or the sale of sexually explicit materials to minors (with an economic motive). The Static-2002R can be used with developmentally delayed offenders, those with symptoms or diagnoses of major mental health issues, and with Canadian Aboriginal offenders.

The Static-2002 and the Static-2002R make use of information commonly available to practitioners in forensics. In particular, there are three basic types of information necessary to score the Static-2002R: offender demographic information, an official criminal record, and victim information. Self-reported information is not acceptable in scoring the 9 items relating to an offender's official criminal record except in rare circumstances (e.g., immigrants, refugees from developing countries). Moreover, the evaluator must come to the conclusion that the self-reported information is indeed credible. Despite the noted limitation of self-report, self-reported information can be used to *supplement* official records. Information derived solely from polygraph sources should not be used to score the Static-2002R unless the information can be corroborated by outside sources. It is possible to score the Static-2002R even if an assessor is missing certain items.

The Static-2002 and the Static-2002R were intended to assess theoretically meaningful characteristics thought to be important to understanding recidivism risk (persistence of sexual offending, deviant sexual interests, general criminality). This being said, experts often disagree about the causal nature of psychological constructs while agreeing that there is practical utility with existing measures, such as the Static-2002R for applied decision-making.

The Static-99 is the most researched of all risk assessment tools for sex offenders, with moderate predictive accuracy (on average). The Static-2002R has a moderate relationship with sexual recidivism. Meta-analysis has found that the Static-2002R has consistently higher AUC areas (i.e., predictive accuracy) than the Static-99 for sexual, violent,

and general recidivism. The Static-2002 and the Static-2002R are noted to predict sexual, violent, and any general recidivism as well as other actuarial risk tools typically used with sexual offenders. In terms of clinical use, the Static-99 is the most widely used measure for assessing risk of sexual recidivism. In a 2009 meta-analysis, there were 63 validation studies of the Static-99 (about twice the number of studies of the next most researched scale). Moreover, the Static-99 and the Static-99 have been the subject of relatively large field and cohort studies. The Static-99 and the Static-2002 have been validated for use internationally and with various ethnic groups.

STATIC-99 AND STATIC-99R

The Static-99 and its revised form, the Static-99R (together referred to as *Static-99/R*), are static, actuarial risk assessment instruments. The Static-99/R is designed for the evaluation of future re-offense risk among adult men, specifically those with a history of sexual offense convictions. It is comprised of 10 items which inventory the offending individual's demographic characteristics and criminal conviction history and the characteristics of the sexual offense victim. Although originally developed in English, the Static-99R has since been translated into several different languages including Chinese, French, and German. At present, the Static-99/R is the most widely used sexual offense

risk assessment instrument in the world. This entry briefly addresses the history of the Static-99/R, then examines the Static-99/R items, criteria for use, and guidelines for interpreting scores.

History

The name Static-99 is derived from 1999, the development year of its original form, and its focus on static, or unchanging, risk factors associated with future sexual or violent offense behavior. It was originally developed following analyses of two separate risk assessment tools: the Rapid Risk Assessment of Sex Offender Recidivism and the Structured Anchored Clinical Judgment-Minimum. Each provided statistically unique contributions to recidivism risk estimates, and a 10-item amalgamation was assembled from these two instruments. In 2009, research demonstrating a correlation between increased age and reduced recidivism risk drove a change in the age item from two categories to four. This represented enough of a substantive change to rename the instrument the Static-99R (i.e., the revised version).

Static-99/R Items

The Static-99/R is completed using information drawn from the offending individual's demographics and criminal history, and sexual offense victim demographics. Some of the Static-99/R items are relative to the *index sexual offense*, that is, the most recent sexual offense (usually the current offense) for which the individual has been convicted and sentenced.

Age at release from index sex offense refers to the individual's age upon placement in the community. This may be the offender's age when sentenced to community supervision in lieu of incarceration or the offender's age at release from jail or prison. The Static-99 only differentiated between younger and older individuals. The Static-99R updated this item to include multiple age cutoffs; research has illustrated recidivism risk reduces with age.

Ever lived with a lover queries the individual's history of maintaining cohabitation with an age-appropriate intimate partner for at least two uninterrupted years. This is believed to reflect skills

associated with reduced sexual offending behavior (e.g., the ability to develop prosocial relationships and engage in interpersonal problem-solving).

Index nonsexual violence—any convictions is counted for any specific convictions for a violent, nonsexual crime, prosecuted concurrent to the index sexual offense. This may include convictions for assault, murder, kidnapping, or robbery. Similarly, *Prior nonsexual violence—any convictions* counts convictions prior to the index offense sanction. While such nonsexual, violent behaviors are often associated with future criminal behavior, these items do not include arrests or charges that do not result in convictions, institutional rule violations, or self-reports of nonsexual violence.

Prior sex offenses includes sexual offense arrests, charges, and convictions recorded prior to the index offense sanction. The number of arrests, charges, and convictions, including those as a juvenile, is converted into a prior sex offense score, depending on the number of each type of sanction. Pseudo-recidivism (i.e., historic offenses adjudicated after the index sexual offense) is not counted toward this score.

Prior sentencing dates counts the number of unique sentencing episodes for any offense prior to the index offense sanction. Four or more prior sentencing episodes are weighted toward increased recidivism risk.

Any convictions for noncontact sex offenses is scored if the individual has been convicted of offenses including exhibitionistic or voyeuristic behavior, offenses related to child pornography, or obscene use of a communications device.

The remaining items, *any unrelated victims*, *any stranger victims*, and *any male victims*, are described as *the three victim questions*. Scoring these items may be based on official information related to the offense but also based on an individual's self-report or other information the evaluator deems credible.

Criteria for Use

The Static-99/R is an actuarial risk assessment tool, and as such, its primary purpose is to inform evidenced-based estimates of recidivism risk. Formal research on the Static-99/R has focused on adult men who have been legally sanctioned for an offense that is sexual in nature. The Static-99/R

is not typically recommended for use with juvenile males who commit sexual offenses and is not recommended for use with female sexual offenders.

A number of criteria adopted by many sexual offense risk assessment instruments originated from or were popularized by the Static-99/R. What follows is a discussion of several key criteria.

Legal Sanctions

To qualify for a Static-99/R scoring, an individual must have been *legally sanctioned* for some criminal sexual behavior, which includes a number of possible legal classifications. While court proceedings involving sexual offenses often result in convictions for a sexual crime, there are many situations in which a specific sexual crime conviction is not achieved, such as a defendant being found not guilty by reason of insanity. Such a criminal charge is still considered a legal sanction necessary for Static-99R use. An arrest for sexually motivated criminal behavior may be classified as a qualifying legal sanction as well; even if the individual is not charged for an offense which is sexual in nature, there can be enough evidence to substantiate a sexual motive or quality to the behavior. Other legal sanctions include institutional disciplinary actions for nonconsensual sexual behavior and violations of probation, parole, or other forms of community supervision.

Offense Categories

The Static-99/R classifies sexual offenses into two categories. Category A offenses include those sexual behaviors involving any child or a nonconsenting adult victim, including rape, child molestation, or exhibitionist behavior. Category B offenses involve legally consented, criminal sexual behavior, including consenting sexual activity between adults in public, or behavior that does not involve an identifiable victim (e.g., behaviors involving child pornography). Individuals who have never been sanctioned for Category A offenses in their lifetime cannot be scored on the Static-99/R.

The Index Offense

A key component of scoring the Static-99/R is the index offense. The index offense is the most

recently sanctioned sexually offense. This may include any new Category A offense, or a Category B offense committed by those sanctioned for Category A behavior in the past. The index offense also contributes to the time reference for the recidivism risk estimates provided by the Static-99/R.

Many individuals' sexual offense histories are complicated, though, and an individual being scored on the Static-99/R may have multiple recent sexual offense sanctions. The following two classifications for multiple offense types have been identified:

Index clusters—An index cluster is identified most simply as several offenses committed during the same period of time. These multiple offenses are investigated and prosecuted as a group, often appearing as a *spree*, or cluster, in one court episode on a criminal record review. Variants of the index cluster are determined by the evaluator scoring the Static-99/R. For example, these offenses may occur in multiple areas, thus causing court proceedings in different jurisdictions. Alternatively, multiple offenses may not all be uniformly identified by the authorities, but nevertheless their proximity in time qualifies these offenses as a cluster.

Pseudo-recidivism—Pseudo-recidivism refers to new sanctions for sexual offending behavior that is substantially older than the index offense. Many sexually offending individuals have previous sexual offenses which are unreported for a variety of reasons but later come to light following the official index sanction. For example, the publicity surrounding an individual's conviction for sexual abuse may encourage victims of previously unreported offenses to come forward about their experiences. As these offenses were never sanctioned before the index offense, they are not counted toward prior sexual offense convictions. Pseudo-recidivism is a class of index cluster but differs from other index clusters in that the time factor between the early offenses and the index offense is distal, not proximal.

Interpreting Static-99/R Scores

The Static-99/R raw score is derived from summation of the 10 items, without further scaling or adjustment. The Static-99's scores ranged from 0 to 12, while the Static-99R range is from -3 to 12.

There are multiple applications of this score to determine the risk of sexual recidivism as well as nonsexual violent recidivism, for a specific individual score on this instrument.

As an actuarial risk assessment instrument, the Static-99/R predicts the probability that a sexually offending individual will be sanctioned again for another offense. For a specific Static-99/R score, several ways of reporting this probability are available. Observed recidivism rates are available from a number of sources; given the lower prevalence of some offender types (e.g., relatively high-risk offenders), a type of statistical modeling known as *logistic regression* may be used to estimate the rate of recidivism associated with a specific score. Alternatively, the risk ratio for a specific score may be reported. The risk ratio is the individual's odds of recidivism against a reference point for the offender population (e.g., the median score of all offenders). These recidivism data are often based on the likelihood of re-offense 5 or 10 years following placement in the community after the index offense.

A key consideration in assessing recidivism predictions is the application of data from an appropriate sample. Users of the Static-99/R must consider the population from which a sexually offending individual originates, then draw conclusions about risk based on information from a sample which most closely fits this population. Some jurisdictions may choose to survey their own population and develop specific, appropriate risk information or norms. However, the Static-99/R undergoes regular evaluation, which includes updating norms based on multiple aggregated samples of offenders. The developer-provided risk norms fall into two categories: routine and preselected high risk. The use of preselected high-risk norms is based on information exclusive from the Static-99/R score, which indicates an individual presents greater recidivism risk than is typical for that individual's Static-99/R score. An example of this includes elevated scores on a separate dynamic risk assessment tool.

It is necessary to be aware of population characteristics to ensure information provided by the Static-99/R is statistically valid in risk assessments. The primary method of evaluating the statistical accuracy of the Static-99/R is the area under the receiver operating characteristic curve (AUC) statistic. This statistic ranges in value from 0 to 1.0; an AUC of 1.0 shows perfect prediction, whereas an

AUC below 0.5 implies more incorrect than correct predictions. A comprehensive meta-analysis of Static-99/R research found an overall AUC between 0.69 and 0.70, which essentially means that there is a 69–70% probability that a randomly selected sexual recidivist will have a higher Static-99/R score than a randomly selected nonrecidivist. However, the AUC value can vary significantly between different populations; ensuring the Static-99/R is valid within a specific population is of paramount concern in risk evaluations.

Static-99/R consecutive scores may be clustered into relative risk categories, traditionally defined as low, low-moderate, moderate-high, and high risk of recidivism. As of 2016, the recommended classification of Static-99R scores involved qualitatively categorizing scores which correlate with psychologically meaningful criteria. A five-category system is used which clusters offenders not solely on the probability of a new offense but on the characteristics of those who fall into a given category. Static-99R scores of 1–3 comprise Category III or the *average risk* category. This suggests individuals in this group are within the average likelihood range of recidivism risk of their jurisdiction. Category-I and Category-II offenders encompass Static-99R scores of –3 to –2 and –1 to 0, respectively, and are typically older and less involved with the criminal justice system than the average risk offender. Category IV-a includes scores of 4 or 5, and Category IV-b includes scores of 6 and above. Each increased level is typically indicative of greater history with the criminal justice system, violent offenses, and other factors associated with persistent sexual offending (e.g., offenses against strangers). These categories more easily communicate an individual's risk potential, while being less subject to differences between jurisdictions or between methods of evaluation.

STATISTICAL INFORMATION ON RECIDIVISM (SIR)

The SIR Scale is a static actuarial risk assessment tool developed and employed within the Correctional Service of Canada for the assessment of risk of general recidivism with adult male federal offenders (serving sentences of a minimum 2-year duration). This entry discusses the development, applications, and validation research of the SIR Scale, including its use with special populations.

Development and Item Content

Developed initially in 1982 by Joan Nuffield, the SIR Scale was constructed and validated on a combined sample of 2,475 adult male federal offenders who were released from 1970 through 1972 and followed up for 3 years in the community. The SIR Scale was developed through what

has become known as the *Burgess method*, that is, by differentially weighting predictor variables shown to successfully discriminate recidivists from nonrecidivists. For each category or value of a predictor demonstrating a 5% increase or decrease in recidivism from the overall rate, a weighting of +1 or –1, respectively, is assigned. The weights are increased in either direction based on the degree of difference from the overall recidivism rate associated with a given category or value on a variable. In this manner, stronger predictors (i.e., variables with the best discriminating power) are given the heaviest numerical weights. As the SIR Scale was developed in a purely data-driven manner in the absence of theory, it is termed an *Empirical Actuarial Scale*.

In the original Nuffield study, the construction sample had a mean 43.9% recidivism rate (i.e., rearrested for a new offense), or conversely, a 56.1% success rate (i.e., were not rearrested for a new offense). The Nuffield scoring of the SIR was conducted in terms of success, or nonrecidivism. For instance, having one or two prior imprisonments was associated with success rates of 55.1% and 53.6%, respectively; as this is less than a 5% departure from the overall success rate in the sample, values of 1 or 2 were assigned a score of 0. Having 0 prior imprisonments, however, was associated with a considerably higher rate of success, 79.1%; given that this is a 23% increase from the overall rate of success, this was given a weighting of $23/5 = 4.6$ or “–4” (values were rounded down). By contrast, having three or four prior imprisonments was associated with success rates of 48.5% and 51.1%, respectively, which are each associated with 7.1% and 5% decreases in success, so they were assigned +1 points each. For this item, this was done up to a maximum of five to eight previous imprisonments, which was associated with success rates ranging from 43.3% to 40.5% (about a 12–15% decrease), and for consistency, a weighting of +2 was assigned.

In total, 15 variables shown to discriminate recidivists from nonrecidivists were identified and given differential weights in this manner. These variables include

- age at admission,
- number of previous imprisonments,
- previous breach of parole supervision or mandatory supervision,

- number of previous escapes,
- security classification,
- age at first adult conviction,
- number of previous convictions for assault,
- marital status,
- interval at risk,
- number of dependents,
- aggregate sentence,
- number of previous convictions for violent sexual offenses,
- number of previous convictions for break and enter,
- employment status at time of arrest for commitment offense, and
- type of commitment offense.

Once scored, the items were simply summed to generate an overall score that was associated with probability of success on release. The SIR was scored in a manner originally, such that higher scores were associated with increased recidivism (or decreased success) and lower scores were associated with increased success on release (or nonrecidivism), with possible scores ranging from -27 to +30. This has since been reversed so that possible scores range from -30 to +27, with lower scores indicating poorer prospects for success upon release. The SIR was divided into five score bands associated with different rates of success or nonrecidivism. In a validation sample of 1,237 offenders, these score bands with associated rates of success were as follows:

- Group 1: *Very Good* (-6 to -27) 84.5% success
- Group 2: *Good* (-1 to -5) 67.9% success
- Group 3: *Fair* (0 to +4), 50.8% success
- Group 4: *Fair to Poor* (+5 to +8) 41.9% success
- Group 5: *Poor* (+9 to +30) 31.6% success

Applications

The SIR Scale has undergone minor revisions in the years subsequent to Nuffield's development of the tool, with the SIR-Revised-1 developed in 2002 and still in use. Note, the term SIR Scale is used throughout this entry for consistency in language. Experimental variations on the SIR and SIR-Revised-1, termed *SIR proxies*, have been developed with parallel item content and similar item scoring and weighting for examination with special populations

for which the SIR Scale had not been originally validated; most notably, female and Aboriginal offenders (discussed below). It is standard operating procedure with the Correctional Service of Canada for parole officers to administer the SIR at the point of intake in the offender's admission to custody in order to evaluate potential for success on release to the community. It is not, however, administered to women or Aboriginal offenders.

The SIR Scale is one important piece of information the Parole Board of Canada uses in evaluating an offender's suitability for conditional release. As the SIR is made up of static items (i.e., historical, and generally unchanging), it cannot assess changes in risk from positive progress made on the individual's correctional plan or resulting from other credible change agents (e.g., specialized treatment completion, improvement in supports, major deterioration in health). For this reason, the SIR is typically supplemented with other measures that assess dynamic (i.e., changeable) risk markers to assess suitability for conditional release. Moreover, although subsequent validations of the SIR have provided some support for the ability of scores on the tool to predict other forms of recidivism (e.g., return to custody for a sexual or violent offense), the SIR Scale is used primarily to forecast probable success in the community or new returns to custody for any new offense in general (i.e., general recidivism).

Subsequent Validations

Subsequent validations of the SIR Scale have reaffirmed its properties for predicting postrelease returns to custody. One of the largest validations was performed in the early 1990s by federal government researchers from the Ministry of the Solicitor General of Canada. In this study, 3,267 male prison inmates released from 1983 to 1984 and rated on the SIR Scale were followed up for a minimum 3 years postrelease. The SIR Scale in this new sample demonstrated similar rates of success and return to custody across the five score bands as in the original Nuffield evaluation. It also displayed impressive predictive accuracy for general recidivism, with an area under the receiver operating curve (AUC) value of .76. With possible values ranging from 0 to 1.0, an AUC value of .76 would be interpreted to mean that there is a 76% chance

that a randomly selected recidivist (for any new offense) would have a worse score on the SIR Scale than a randomly selected nonrecidivist.

As the volume of research on the SIR has accumulated, meta-analyses have been possible to examine how well the SIR and its variants predict different forms of recidivism, although most of these reviews have examined how the SIR has fared in specific offender populations, such as sexual or violent offenders. Two meta-analyses that examined the prediction of violent recidivism in violent offenders found the SIR Scale fared reasonably well, with AUC values ranging from approximately .63 (17 studies) to .68 (three studies). A further major meta-analysis published in 2009 of recidivism prediction among men who committed sexual offenses yielded similar findings. Specifically, AUC equivalents were obtained for the prediction of sexual recidivism (AUC = .64, five studies), violent recidivism (AUC = .71, three studies), and general recidivism (AUC = .76, four studies). In all, the existing research to date has supported the predictive accuracy of SIR scores for return to custody, particularly when it comes to assessing risk of any (i.e., general) recidivism.

Research With Special Populations

In 1988, it became policy within the Correctional Service of Canada to not administer the SIR Scale to persons of Aboriginal ancestry owing in part to the limited research available at the time. At least four evaluations to date conducted by Canadian federal government researchers have examined the properties of the SIR Scale or the SIR-Proxy with Aboriginal men and Aboriginal women federal offenders. Two early evaluations of the SIR with Aboriginal men in 1989 ($n = 49$) and 1993 ($n = 269$) found the SIR Scale had acceptable accuracy for predicting general recidivism with AUC values in the low .70s. Much larger subsequent examinations of the SIR-Proxy with Aboriginal men in 2002 ($n = 1,211$) and 2012 ($n = 2,560$) found that it predicted sexual (AUC = .60 and .62, respectively), violent (AUC = .63 and .57, respectively), and general (AUC = .68 and .63, respectively) recidivism. Of note, the effect sizes for the latter two evaluations tended to be higher for non-Aboriginal offenders in the prediction of general and violent recidivism but were

higher for Aboriginal offenders in the prediction of sexual recidivism.

The latter two studies benefited from a large sample size, which enabled them to examine the SIR-Proxy among female offenders, including Aboriginal and non-Aboriginal subgroups. In the subset of 342 women offenders from the 2002 evaluation, the SIR-Proxy showed good predictive accuracy for general (AUC = .77) and violent (AUC = .73) recidivism. The larger 2012 evaluation similarly found the SIR-Proxy to predict general and violent recidivism among 246 Aboriginal (AUC = .65 and .70, respectively) and 666 non-Aboriginal (AUC = .74 and .82, respectively) women. Although prediction effect sizes among male and female offenders did not appear to differ substantively, again, prediction magnitudes were somewhat higher for non-Aboriginal offenders with respect to violent and general recidivism.

Final Thoughts

The SIR Scale continues to be a primary risk assessment tool to assist in appraising suitability for conditional release and prospects of postrelease success among adult male, non-Aboriginal federal offenders in Canada. As a static actuarial tool, the SIR is limited in its ability to assess change but is a useful complement to other general and specialized dynamic measures that can track progress and change. Although psychometric research to date demonstrates that the SIR Scale and its variants can predict recidivism among special populations, such as women and Aboriginal offenders, at this current juncture, the tool is not used with these groups, and alternative measures are used instead to aid in the assessment and management of risk.

STRAIN THEORY OF CRIME

Strain theories of crime propose that people are pressured into crime through experiencing stressful events. Classic strain theories focus on the mismatch between the desire to obtain monetary success and the opportunity to achieve it. Those who experience this type of strain (i.e., the lower class) may choose crime as a way to achieve their goal of obtaining middle-class success. Given that people experience many different types of strain beyond financial-related strain and those who are part of the middle class engage in crime as well, Robert Agnew developed general strain theory (GST) to expand on the shortcomings of classic strain theories. This entry describes the history of strain theory as well as the assumptions and concepts of GST, then explores how GST has been applied to explain group differences as they relate to crime.

Historical Background of Strain Theory

Anomie Theory

Robert K. Merton's 1938 publication spurred the development of two related theoretical traditions, anomie theory and strain theory. Merton argued that when the goals of middle-class financial success were emphasized in the absence of the same weight placed on the legal means to achieve it, anomie results. Anomie theory is a macro-level

theory designed to explain differences in crime rates among societies, including why places like the United States have higher crime rates than other countries. In 1994, Steven F. Messner and Richard Rosenfeld expanded this idea to argue, in their institutional anomie theory, that the United States in comparison to other industrialized nations places a strong emphasis on the *American Dream*, or a culture of individual financial success. Therefore, in the United States, the economic institution dominates in importance compared to other institutions such as the family, educational system, or the polity, and the values of the economic system are infused into these other institutions, inhibiting their effective operations. For example, similar to the economic institution, the education system prioritizes rewards based on competition rather than learning as a key goal. Crime rates are proposed to be higher in societies when a high level of anomie exists along with a dominant economic institution. Research has found that when the economic institution has more importance in a society than institutions, such as family, religion, and education, crime rates are higher. It has been more methodologically challenging for researchers to test the ideas that the United States has higher crime rates than other places because citizens strongly desire the economic goals while deemphasizing the legal means to achieve them. The findings from a limited number of studies provide mixed support for this part of institutional anomie theory.

Classic Strain Theory

At the microlevel, Merton examined the consequences of anomie when individuals experience a disjuncture between the cultural ideas of economic success and the legitimate opportunities to attain them. As a result of this strain, individuals may adapt in five different ways: conformity, innovation, ritualism, retreatism, and rebellion. First, most individuals will choose to conform to the cultural goals of striving to achieve economic success and pursue the legal means to accomplish these goals (e.g., going to college). Individuals who fall under the innovation category, which is the most common deviant response to strain, accept the cultural goals but realize they will not be achieved through legitimate channels so they

resort to illegal options (e.g., becoming a drug dealer). Ritualists reject the cultural goals that are outlined by society; however, they accept the means of achieving the goals. An example of these individuals may be those who in low-paying jobs with few opportunities for advancement. These individuals may not have any aspirations to advance, but they continue to follow the norms required of their work. Retreatism is the mode of adaptation when individuals reject the cultural goals and the means of achieving these goals, essentially withdrawing from society possibly through drug or alcohol addiction. Those who rebel (rebellion adaptation) reject both cultural goals and the legitimate channels of achieving the monetary goals. For example, a person who tries to violently overthrow the government in order to substitute the cultural values with their own goals would be an example of adapting to strain through rebellion.

Albert K. Cohen and Richard A. Cloward and Lloyd E. Ohlin in the 1950s and 1960s extended classic strain theory to explain how individuals who experience strain are less likely to engage in crime unless they become part of a delinquent subculture whose main values are centered on crime. In addition, Cohen stated that economic success is not the only important source of strain for those with blocked opportunities. Rather, lower class youth do not have the verbal or social skills to obtain middle-class status and as a result reject mainstream values of trying to do well in school and working hard to get ahead.

In the late 1960s and 1970s, classic strain theory was critiqued for lacking empirical support. In addition, much of the literature of classic strain theory failed to discuss delinquency among middle- and upper-class families. Robert Agnew expanded on classic strain theories through developing GST which addressed many of these critiques.

GST

Agnew provides one of the most influential expansions of Merton's ideas at the social psychological level with his development of GST. He argues that individuals experience a variety of strains, including criminal victimization, peer abuse, discrimination, and the inability to achieve autonomy, which then lead to negative emotions such as anger,

frustration, depression, and fear. Anger is more likely to lead to crime given that this emotion reduces the likelihood that individuals will think through their actions, is associated with a desire for revenge and blaming of others, and invigorates individuals to react to the strain. Overall, research shows that strain leads to anger and anger then leads to crime, although some studies do not find this proposed relationship. The roles of other negative emotions in GST are either understudied or provide mixed support.

Strain may lead to crime through other avenues including reducing social control, facilitating personality characteristics compatible with crime, and increasing the learning of crime. For example, strains which involve being treated negatively by others (e.g., being ridiculed by others or being fired from a job) can lead individuals to withdraw from law-abiding others which reduces social control. In addition, strains such as those associated with poor parenting (e.g., harsh or inconsistent discipline) can foster personality characteristics in an individual which are related to crime, such as being quick to anger or being impulsive. Finally, some strain may encourage individuals to become a part of criminal groups in order to reduce the strain. For example, becoming involved with others who sell drugs may be an appealing option when individuals cannot obtain their financial goals.

Strain can be classified into three broad categories: (1) the failure to achieve positively valued objectives, (2) the loss of something valuable to the individual, and (3) being treated negatively by others. Failing to achieve an objective may include not obtaining the job which is desired. Someone loses something of value when a family member passes away or a significant other breaks up with him or her. Finally, being treated negatively by others may include emotional or physical abuse from peers or family members. Some strains may be disliked by many, if not most, people; these are referred to as *objective strain*. On the other hand, strains may be deemed as stressful for one person but not as stressful for another; these are referred to as *subjective strain*. Agnew further distinguishes among experienced, vicarious, and anticipated strains. *Experienced strains* are those that an individual personally endures. *Vicarious strains* are events experienced

by others around the individual, especially those to whom the individual is closest (e.g., family or friends). Finally, *anticipated strains* include strains that the individual expects will continue into the future or new strains the individual is likely to face.

Given that not all strains result in crime, Agnew describes the characteristics of strain most likely to be related to crime: (a) high in magnitude, (b) perceived as unjust, (c) associated with low social control, or (d) create some pressure or incentive for criminal coping. High in magnitude refers to strains that are perceived to be more severe due to being greater in degree, including a substantial financial loss, occurring recently, over a long period of time, and/or likely to persist. In addition, severe strains threaten an important identity, need, or goal of the individual (e.g., masculine identity). Unjust strains refer to those in which an individual feels he or she has been intentionally mistreated without provocation. Strains which are associated with low social control include those that weaken bonds with others (e.g., being fired from a job or being physically or emotionally abused). Strains which are characterized by pressure or incentives for criminal coping are those which are easily alleviated through crime (e.g., a desperate need for money or strains in which peers encourage criminal coping).

Even when strains are high in magnitude, unjust, are associated with low social control, and could be easily resolved through crime, most individuals do not commit crime. Specifically, individuals vary in their coping skills and resources which may serve to reinforce or reduce criminal coping. For example, individuals who are more impulsive and easily angered are more likely to respond to strain with crime. In addition, when individuals have little to lose such as a good job or quality relationship, they are more likely to commit a crime in order to cope with strain. Finally, individuals who do not believe crime is wrong and/or who have peers who provide criminal models are more likely to respond to strain with crime. On the other hand, having more coping skills including problem-solving skills and emotional and spiritual coping skills or occupying more diverse roles reduces the likelihood that individuals will respond to strain with crime.

Applied GST: Understanding Group Differences in Crime

GST has been applied to understanding group differences in crime including race and gender as well as patterns of offending over the life course. Research supports that while African Americans experience more crime producing strains such as discrimination and financial strain, they also have coping resources available to them to alleviate the strain including strong family ties and religiosity. These counteracting mechanisms can explain why the relationship between race and crime is not strong in self-report surveys.

Gender differences in offending have been explained through differences in the types of strains experienced with males experiencing crime-inducing strain including criminal victimization and threats to masculine identity. On the other hand, females are more likely to experience strains which serve to increase social control including taking care of children or elderly parents. In addition, the gender gap in offending has been explained by differences in the experience and expression of emotions. In particular, evidence suggests that females experience anger at similar or even greater levels than males but factors such as simultaneously experiencing emotions such as depression suppress the desire to act out. Factors including gender identity or how masculine or feminine individuals are and differences in coping resources provide an explanation for why males offend more frequently than females. Finally, GST can be applied to understanding why offending peaks in adolescence given that the expanding social networks in secondary school increase the likelihood of individuals being treated negatively by peers and romantic partners.

STRATEGIC TRAINING INITIATIVE IN COMMUNITY SUPERVISION (STICS)

The STICS is a model of community supervision based on the Risk-Need-Responsivity (RNR) principles, designed specifically to implement these principles into sustainable everyday action at the organizational and officer level. STICS was developed in 2006 by a Canadian team of researchers (James Bonta, Guy Bourgon, and Tanya Ruge) after their meta-analysis that found the effectiveness of probation services in reducing recidivism was minimal.

The STICS model shifts community supervision practices away from the traditional case-management model to one that emphasizes officers taking a more active role by teaching prosocial cognitive and behavioral skills to their clients. STICS incorporates a holistic cognitive behavioral model of human behavior with the RNR principles as the foundation. Implementing the STICS model begins with a formal 4-day training to officers, which focuses on required skills and intervention techniques. This is followed by a set of structured ongoing professional development activities as well as a series of organizational strategies to ensure fidelity and sustainability. STICS was

initially tested in three Canadian provinces from 2007 to 2009 and demonstrated significant enhancement of the quality and use of STICS skills and intervention techniques by officers and decreased offender recidivism. By 2015, STICS has been fully adopted by two provinces.

Effective Correctional Services: Setting the Stage for STICS

The RNR principles of effective correctional interventions were first described in 1990. These principles linked effectiveness to services provided to higher risk offenders (Risk principle), that targeted criminogenic needs (i.e., empirically related to reoffending; Need principle); and used cognitive behavioral treatment methods that are tailored to the offender's learning style, motivation, abilities, and strengths (Responsivity principle). The robustness of the RNR model has continued to grow through extended meta-analyses of the offender treatment literature and independent tests of the principles. With its accumulated evidence to date, RNR is the predominant model in the rehabilitation of offenders.

With the majority of offenders in North America under a sentence of probation or some other form of community supervision such as parole or bail, applying the RNR principles to community supervision has been viewed as an efficient and effective method to reduce recidivism. In general, community supervision is less expensive than imprisonment, and it is believed to be more effective than custody in reducing reoffending. However, studies that actually examined the interactions between probation officers and their clients cast some doubt on the efficacy of probation officers in promoting change and reducing reoffending. In a 2008 meta-analysis of the effectiveness of community supervision, it was found that community supervision was associated with a reduction of only 2 percentage points in recidivism. Furthermore, more recent studies examining audio-recorded interviews between probation officers and their clients revealed that supervising officers adhered to relatively few of the RNR principles of effective correctional services.

Although the majority of the RNR evidence has examined studies of treatment program effectiveness, early work exploring interactions between probation officers and their clients suggested that

the RNR principles were also applicable to community supervision practices. For example, reduced recidivism was linked to probation officers' utilization of what has been called *Core Correctional Practices*, a variety of skills derived from the RNR model. These Core Correctional Practice skills included certain relationship skills, prosocial modeling, the effective use of reinforcement and disapproval, and problem-solving.

Guided by this empirical knowledge base, community correctional agencies have made efforts to improve the effectiveness of community supervision. However, translating empirical knowledge into system-wide everyday practice has proven difficult as research has illustrated that the effect of RNR-based services diminishes when it moves from a demonstration project to a real-world application. With discrepancies between expectations based on small-scale, well-controlled studies and what was found in large-scale implementations of *what works*, there has been a growing interest in the importance of program design and the integrity of implementation.

It is within this context that an empirically based RNR model of community supervision was developed. STICS was designed as a community supervision officer training program and implementation method intended to ensure fidelity and sustainability of effective community supervision practices.

Development of the STICS Model

The primary goal of STICS was to translate RNR into sustainable everyday practice of probation officers. The STICS development team focused step-by-step on the program design, strategized on how to ensure high-quality implementation, and designed a comprehensive evaluation. Firmly rooted in the general personality and cognitive social learning theoretical perspective and RNR principles, STICS is a community supervision service model and implementation training package that emphasizes officers' teaching skills and providing interventions that facilitate prosocial attitudinal and cognitive change in moderate- to high-risk offenders. Procriminal attitudes and cognitions, arguably the most predictive dynamic criminogenic need, are the primary targets for change. Probation officers are provided with intensive training in the STICS model whereby

they learn and practice a variety of skills and specific intervention techniques.

To maintain fidelity and facilitate sustainability, STICS ongoing professional development includes various learning activities such as monthly meetings that provide practice opportunities and support, regular refresher workshops, and the provision of feedback on the use and application of STICS concepts, skills, and techniques—all designed to consolidate skill development. Implementing STICS requires organizational changes as well, such as increases in staffing and work responsibilities and potential changes in policy and procedures to ensure congruence with the STICS model.

The STICS Model

After more than a year in development (2005–2006), the STICS model consisted of a 3-day initial training course and a series of ongoing professional development activities. The initial training included discussions about the research that led to the development of STICS, what was known to be effective in offender treatment and why, as well as methods to practically apply the principles of Risk, Need, and Responsivity in individual work with clients. Particular emphasis was placed on the skills and intervention techniques required for officers to effectively facilitate change in clients' procriminal thinking and attitudes.

Officers were provided with structures to follow in each supervision session as well as throughout the supervision period. They were taught a variety of skills and intervention techniques including active listening, giving effective feedback, identifying procriminal attitudes, role clarification, collaborative goal setting, cognitive behavior sequencing, countering problematic thinking, prosocial modeling, effective reinforcement, effective disapproval, rehearsal strategies, and problem-solving. Officers practiced through experiential exercises in the training and afterward in the ongoing clinical supervision and professional development activities. In each office, a coach held monthly meetings to provide regular opportunities for officers to practice the skills and techniques, as well as co-facilitated yearly refresher courses, and supported the submission of audio-recorded supervision sessions with clients for which officers received written feedback on the skills and techniques that were employed. With

STICS's emphasis on directly facilitating client change rather than relying solely on formal treatment programs and services, as well as the impact of new job responsibilities and tasks for officers, organizations who adopt STICS were required to adjust their existing workload expectations and staffing resources.

STICS Evidence

In 2006, the STICS model was piloted and evaluated in three Canadian provinces. Eighty probation officers were randomly assigned to STICS training or routine supervision and their supervision sessions were audio-recorded at the beginning of supervision, 3 months later, and 6 months later. Reconvictions statistics for their clients were collected 2 years later. The results of this study suggested that STICS was having a significant impact. First, officers spent significantly more time discussing criminogenic needs with their clients and in particular, talking about pro-criminal cognitions. Second, the probation officers significantly enhanced the use of and quality of the set of evidence-based skills and intervention techniques following training. Third, the results showed continuous development and improvement of these skills and intervention techniques with engagement in post-training clinical support services highlighting the importance of these services. Finally, the reconviction rate for the clients of the STICS officers was 15 percentage points lower compared to the control group clients, and the rate was even lower for clients of probation officers who more fully participated in the ongoing professional development activities.

Following completion of the initial pilot, the STICS team made changes to the STICS training and implementation package. The modifications were as follows: greater emphasis on the cognitive intervention techniques, enriched clinical support activities (e.g., monthly meetings included more structured learning and practice exercises), and improved implementation strategies (e.g., greater support and learning opportunities for coaches to enhance their STICS expertise). These changes were based on the findings from the pilot, feedback received from officers, observations during delivery of training and ongoing learning activities, as well as the application of the model within organizations.

As of September 2018, research and wide-scale implementation is continuing with STICS. Recidivism outcomes are not yet available, but preliminary results support the earlier findings of the pilot. Officers who participate in STICS spend more time discussing client's criminogenic needs and their problematic thinking and are using the STICS skills and intervention techniques more frequently and with higher quality. Evidence also suggests that the STICS approach toward ongoing learning and professional development is having its intended effect.

Moving Forward With Effective Community Correctional Practice

STICS is one of the first RNR-based initiatives that focused on the interaction between probation officers and their clients, attempting to address a multitude of factors that have hindered the translation of empirical knowledge into everyday community supervision practice. STICS includes a model of human behavior and change within the context of community supervision that officers understand. At its core, STICS is a training program designed to enhance officers' use and quality of RNR-based skills and intervention techniques to directly facilitate change in offenders.

STICS is also an implementation model, a package that attempts to address organizational considerations and provide strategies to enhance the implementation, fidelity, and sustainability of evidence-based practices. STICS has a commitment to continual research and evaluation. This commitment looks not only to build knowledge of what works but also to better understand how empirical knowledge can be translated, implemented, and sustained in the practical everyday world of community supervision. The RNR model provides a unifying lens and guidance to better understand how correctional agencies may facilitate and support clients moving away from criminal activity, but there is still much to be learned. Further exploration and identification is needed regarding the various cognitive and behavioral changes of clients that lead to prosocial behavior, of the specific skills and intervention techniques used by officers to facilitate change, as well as the factors that influence and mediate the fidelity and sustainability of evidence-based implementation efforts. Research on STICS and other similar

efforts will continue to aid in the evolution of effective community supervision.

STREET GANGS

Not all gangs are created equal. Although there is no strictly agreed upon definition of what a street gang is, there are certain common characteristics that street gangs possess. There is a group element where the gang serves as a surrogate family for many of the members. There is no such thing as a one-person gang. Symbols are also important to identify who is a member of which gang, and these symbols also create a sense of collective identity.

There are nonverbal (e.g., graffiti) and verbal (e.g., code words) forms of communication that let others know who is part of what gang and the location of a certain gang’s turf. Street gangs also maintain an element of permanence, meaning that they stick around for extended periods of time. The most unique feature of street gangs that differentiates them from prison or motorcycle gangs is their street orientation. Although not every street gang claims turf, it is a common phenomenon among street gangs to place importance on defending their turf. Finally, the key feature of gangs that separates them from any other group is their involvement in crime. When gang members are asked what the gang means to them, they highlight the importance of the gang as a family and their involvement in crime.

Street gangs are an important feature of the criminal landscape in the United States. These groups are hotbeds for criminal activity. According to the 2012 National Youth Gang Survey, conducted by the Office of Juvenile Justice and Delinquency Prevention, there were an estimated 30,700 gangs, 850,000 gang members, and 2,363 gang-related homicides in the United States. To take a closer look at the peculiarities of these groups, this entry follows the career of a typical street gang member, highlighting the general characteristics of gang members, why they join gangs, the gang structure, the types of crime gang members participate in, and the eventual departure from the gang.

Gang Members

Street gang members are not identical, but there are patterns that arise in age, gender, race and ethnicity, socioeconomic status, and place of residence. Individuals who typically join gangs enter in middle school or the early high school years. The average age of a street gang member is 14–18 years, but there are of course gang members who are much older or younger. The majority of gang members are male, but that is not to say that females are not involved in gangs as well. When it comes to race and ethnicity, those considered to be from the lower rungs of the social ladder are typically those who are joining gangs. This trend can be seen historically. When Italians and Irish were the majority of the immigrants coming to the

United States in the 1800s and early 1900s, they were often considered to be on the lower end of the social ladder by U.S. citizens. These were the groups that were forming gangs. Blacks and Hispanics are now often considered the lower rungs of the social ladder, which is why they make up the majority of the gang population. These individuals are drawn from poorer households in densely populated urban cities and neighborhoods. As the next section will illustrate, being in a poor area does not mean an individual will automatically join a gang. Gangs are also not restricted to the poor, and in fact, there is a growing amount of middle- and upper-class youths who are joining.

Joining the Gang: Why and How

When thinking about the process of a joining a gang, one must differentiate risk factors from motivations. As mentioned earlier, living in a poor neighborhood does not automatically make someone join a gang, but that is considered a risk factor because that individual is in closer proximity to gangs in the area. Those living in areas where there are no gangs are not at the same risk of joining than someone living in an area full of gangs. Other risk factors include poor educational or employment potential, poor parental supervision, and exposure to antisocial peers.

Motivations for joining gangs are more subjective to the individual and do not take into account external risk factors like poor neighborhoods and low employment. Family members or peers already in the gang could influence an individual into joining; this is considered a *pull*. Being pulled into the gang means that the individual is drawn by the gang's offers. Along with the family aspect, other pulls include protection, money, and a sense of status. For many ethnic Hispanic gangs, membership represents a source of cultural honor. There are also gang members who are *pushed* into joining gangs. Being pushed into a gang is akin to being forced to join the gang. For example, an individual may fear physical consequences of not joining and may feel compelled to join.

The actual process of being initiated into the gang introduces the individual into the violent culture of the gang. With this initiation, individuals are *jumped* or *beaten* in. This process looks

similar across gangs in cities across the country. The potential member is forced to take a beating from the members of the gang. The potential member is either jumped in, or they must complete a mission against a rival gang. This mission usually involves the murder of a rival gang member. This initiation process shows new members that violence is important to the gang and is expected.

Gang Structure

One of the reasons why gangs are not all the same is because there are varying levels of organization among different gangs. Some gangs are more organized and some are less so. A gang's organization is dependent on how well they are able to carry out their activities. A gang that is able to give commands and successfully engage in illicit operations is more organized than a gang that has difficulty in doing so. There are two perspectives with gang organization. The instrumental-rational approach believes that gangs are organized and have a hierarchical leadership structure and that there exists discipline, well-defined roles, and rules of conduct. The unorganized perspective is the informal-diffuse approach. This approach considers gangs to be a group of poorly unified individuals who loosely pursue the group's interests but are mainly committed to individual self-interest. Street gangs are more likely to be disorganized than organized. Again, these gangs are typically filled with adolescent individuals who have little to no training in management or organizational efficiency.

Gangs that have certain organizational characteristics, either in higher quantity or quality, are considered more organized than those who do not have these characteristics. Gangs that have been around longer are usually more organized than brand-new gangs because they have had more of an opportunity to define leadership roles and structure. Gangs that have rules are more organized than gangs that allow their members do whatever they please. The most organized gangs even have written constitutions that detail rules of conduct. Very much like the criminal justice system, gangs have systems of punishment if one of their members falls out of line and breaks the rules of the gang. Gangs that have specialized roles are

more organized than gangs with no differentiation in membership. There are typically three levels of roles in gangs: leaders, experienced gang members, and regular members. Those who are leaders or experienced gang members are more committed to the gang. Regular members could include those on the fringe of the gang or those who have not proven yet that they have a strong commitment to the gang.

Another characteristic of gang organization is gang meetings. Most gangs hold meetings, but for some of the larger gangs, it would be impractical to have every member attend, so usually key leaders and decision makers attend these meetings and disseminate the information to the other members. Some gangs, such as the Gangster Disciples, are so organized that they have strong influences in the political, social, and economic landscape in the areas they reside. There are also some gangs that are so unorganized that they dissipate in a short amount of time.

Types of Crimes

Gangs and gang members do not specialize in specific types of crimes. Gang membership influences all types of criminal behavior. One of the more prominent offenses that gangs participate in is drug use. There is a general consensus among gangs that marijuana usage is fine, but once harder drugs (e.g., cocaine, heroin) are involved, this consensus begins to fade. Many members claim that usage takes away from the group's overall profits. Those gangs that are more accepting of harder drug usage are also the gangs that are less organized and have less authority over what their members do.

Apart from drug usage, gang members are also often involved in drug dealing. Not every gang is involved in drug dealing to the same degree. The more organized a gang is the more likely they are able to handle larger quantities for distribution. It is more common to see members sell drugs for themselves.

Gun ownership and carrying has symbolic significance and is another widespread act that gang members participate in. The gun is a symbol of power in the gang world. It is perceived to be necessary for protecting oneself against potential

attacks from rival gang members. Gang members are more likely to carry guns than nongang members, which could be one of the main influences on their criminal behavior.

Gang members also participate in serious violence at higher rates than nongang members. They must defend their turf from rival gangs, usually by force. They complete missions on rival gangs by participating in drive-by shootings. By being in a gang, an individual is more likely to be a victim of violent crime than the nongang member. Not every gang member is equally involved in gangs, however, so not every gang member is necessarily at the same risk of participating in violence or being victimized. Violence is expected from leaders, who are likely to be high-profile targets for rival gangs, but these expectations are relaxed for fringe members who are not often exposed to the same volume of gang activities.

Leaving the Gang: Why and How

Contrary to popular belief, the average length of gang membership is 1 year. Similar to joining gangs, push and pull factors play an important role in the departure from the gang. Push factors are those internal to the gang that makes membership undesirable. For example, the constant fights and violent lifestyle eventually make membership undesirable and members feel the push to leave the gang. Pull factors are external to the gang and guide a member out of the gang. These factors are typically jobs, social interventions, children, and/or romantic relationships. Gang researchers David Pyrooz and Scott Decker found that two thirds of former youth gang members studied left because of push factors instead of pull factors. So in an ironic turn of events, many of the reasons why people join gangs become the reasons why they leave.

Depending on the gang and the reason for leaving, this departure process could be painless or painful. Departing members could be met with hostile or nonhostile rituals. Many of the same methods for initiation are used for when a member leaves the gang. They could be beaten out, commit a mission against a rival gang, or be forced to shoot a family member, typically the individual's mother. That said, Pyrooz and Decker

found that only 20% of gang members in their sample were sent off hostilely. For the most part, the gang understands the pressure to leave and sends off the member peacefully.

STRUCTURED ASSESSMENT OF PROTECTIVE FACTORS (SAPROF)

The SAPROF for violence has been under development since the early 2000s. Arguably, it represents one of the most systematized attempts at creating an adult-focused protective factor assessment tool that mirrors the structure commonly found in other risk assessment tools. It joins a relatively small but growing group of forensic tools incorporating protective or strength-based factors (i.e., any characteristics of an individual person, his or her situation, or environment that may reduce the risk of future violence) into violence risk assessment, such as the Structured Assessment of Violence Risk in Youth, the Inventory of Offender Risk, Need, and Strength, and the Short Term Assessment of Risk and Treatability. This entry addresses the basic structure of the SAPROF and the relationship between protective factors and risk factors, evaluates the role played by the SAPROF in predicting future violent offending, and explores other possible uses of the SAPROF.

Basic Structure

The SAPROF is comprised of 17 hypothesized protective factors, which are subdivided into five internal characteristics, seven motivational factors, and five external factors. Two internal characteristics (i.e., intelligence and secure attachment in childhood) are viewed as static variables (i.e., generally unchanging with time or intervention), whereas the remaining 15 items are hypothesized to be dynamic variables (i.e., potentially changeable).

<i>Internal</i>	<i>Motivational</i>	<i>External</i>
1. Intelligence	6. Work	13. Social network
2. Secure attachment in childhood	7. Leisure activities	14. Intimate relationships
3. Empathy	8. Financial management	15. Professional care
4. Coping	9. Motivation for treatment	16. Living circumstances
5. Self-control	10. Attitudes toward authority	17. External control
	11. Life goals	
	12. Medications	

Each item is rated as 2, 1, or 0 to represent whether the factor is present, partially present, or absent (as per the operational definitions and rationale in the administration manual). A total protection score can then be calculated. Final protection ratings are assigned using structured professional judgment rather than relying on actuarial derived protection bins. Additionally, the authors, Vivienne de Vogel, Corine de Ruiter, Yvonne Bouman, and Michiel Vries Robbé, argue that the SAPROF is best used in combination with a risk-focused assessment tool, such as the Historical, Clinical, and Risk Management-20 (HCR-20). Should clinicians choose to pair the HCR-20 with the SAPROF, the SAPROF protocol allows clinicians to make integrated final risk ratings after reviewing the HCR-20 and SAPROF together. Finally, clinicians can also identify which factors are *key* to the offender's evaluation, which factors should be treatment *goals* for the offender, and whether other considerations are worth noting.

Due to its recent publication, the current literature on the SAPROF's psychometric properties, predictive accuracy, and usefulness is relatively small but rapidly growing. Studies examining the SAPROF have demonstrated support for its use with a range of populations. Reception of the SAPROF by the academic community has been largely positive; however, it has not been without criticism.

Protective Factors Versus Risk Factors

Protective factors have long been included as an under-addressed and under-researched component of effective correctional treatment. The SAPROF conceptualizes protective factors as any characteristics of an individual person, his or her situation, or environment that may reduce the risk of future violence. A major criticism of the literature on protective factors is a lack of a mutually agreed upon conceptual and operational definition regarding what constitutes a *protective* factor, and by what mechanism they impact offending. Some authors view protective factors and risk factors as the same construct in that the presence of one categorically means the absence of the other (e.g., the presence of the risk factor *dysfunctional parenting* would translate to the absence of the protective factor *secure childhood attachment*). Many researchers use the terms *protective factor* and *risk factor*

interchangeably. If such a relationship is true, then protective factor tools would not, in fact, assess protection but rather provide reverse assessments of risk. Thus, any relationship between protection and offending would actually just be a proxy of the relationship between risk and offending.

Such a criticism could be made about some components of the SAPROF. In numerous published studies, many of the SAPROF items as well as its total score have been found to correlate highly with the risk factors and total score of the HCR-20. For example, the SAPROF's *self-control* protective factor is defined as the absence of impulsivity; *impulsivity* is a risk factor on the HCR-20 and is largely defined as the lack of self-control and inhibition. Correlations between these 2 items generally range between $-.60$ and $-.76$. Additionally, many of the SAPROF items share marked similarities with the Big 4 and Central 8 risk factors. The authors of the SAPROF acknowledge this criticism in the administration manual and note that most of the SAPROF's protective factors could also be considered risk factors. The authors acknowledge that the concept of protective factors is ambiguous, and they openly discuss the conceptual difficulties in defining protective factors.

Other possible relationships between protective factors and risk factors warrant discussion:

1. Protective factors and risk factors could represent opposite poles of a continuum; that is, the factor could be protective at one end of the continuum, risky at the other end, and neither risky nor protective toward the middle of the continuum. For example, the absence of the risk factor *antisocial peers* does not necessarily mean the presence of the protective factor *prosocial peers*.
2. Protective factors and risk factors could represent completely unique and independent factors. Therefore, they would not correlate with each other and an offender could be high in both protection and risk. Currently, the research literature does not support this possibility.
3. Protective factors are actually resilience factors. Resilience can be defined as the capacity to adapt successfully in the presence of risk and adversity. Research on resilience factors in offending similarly struggles with mixed findings and its own conceptual issues (i.e., Are they traits? Are they teachable? Are they universal?).

Subsequent to resolving these conceptual and operational definition issues, mechanisms of action still need to be clarified. Possible mechanisms include direct effects, buffering or mediating effects (either fully or partially), and moderating effects. It is also possible that specific protective factors may only have protective effects in the presence of a specific risk factor. That is, protective factors may not have a global protective effect on offending but rather have smaller moderating effects only when specific risk factors are present. Further research elucidating these processes is clearly required.

Role of the SAPROF in Predicting Future Offending

Although conceptual issues remain regarding the exact nature of the SAPROF's protective factors, the research literature has been supportive of its ability to predict future nonviolent, violent, and sexually violent offending. This relationship has been observed in a number of populations including male and female offenders; correctional, not criminally responsible, and mentally disordered offenders; psychiatric and incarcerated populations; and over many different follow-up periods (ranging from 1 to 10+ years post-assessment). Predominantly, this research has been conducted in European settings; however, recent research in Canada seems to be equally favorable. The magnitude of the SAPROF's predictive accuracy appears similar to that of other risk assessment tools. As such, it is unlikely that the SAPROF is superior or inferior to the other mainstream risk assessment tools in its ability to predict offending.

Since the SAPROF's predictive accuracy has largely been established, current research seems to focus on testing its internal assumptions as well as whether it adds uniquely to the prediction of offending that is not otherwise accounted for by risk. A major assumption of the SAPROF is that 15 of its protective factors are dynamic. In order to establish dynamism, one must measure the factor at a minimum of two time points, that an intervention occurs between these two time points, that the factors change in response to the intervention, and accordingly an increase or decrease in an outcome variable is observed (in this case, increases

or decreases in offending). Research in both European and Canadian samples has demonstrated that scores on the SAPROF's dynamic factors do significantly change with time and intervention; however, demonstrating that these changes reflect actual changes in future offending rates has been less positive. For example, in a study of high-risk/low-protection Canadian offenders who underwent an intensive RNR-based violence treatment program, level of protection on the SAPROF was significantly higher posttreatment; yet, these increases in protection only minimally to moderately corresponded with reductions in future reoffending. Clearly, more investigation is necessary.

A second major area of research on the SAPROF focuses on whether the SAPROF uniquely adds to the prediction of offending beyond that captured by other risk assessment tools. Studies examining whether the SAPROF adds incrementally to the prediction of the offending over the HCR-20 has been mixed. Many studies have demonstrated incremental contributions for a subset of offending types, but which type of offending the SAPROF incrementally predicts appears to vary from study to study. Recently, in a Canadian sample of incarcerated high-risk violent offenders, the SAPROF did not add incrementally to the prediction of any offending types over the HCR-20 despite showing strong independent predictive accuracy. These results do raise the question that even if the SAPROF does add incrementally to the prediction of reoffending, such contributions may be small and may not markedly change a clinician's final risk ratings. As such, more research is needed to establish whether the SAPROF consistently adds both incremental and clinical meaning to the prediction of all offending or only to specific populations and to specific offense types.

Other Uses and Future Directions of the SAPROF

Although the SAPROF has been demonstrated to predict offending, its authors argue that its greatest value relates to guiding treatment planning. This line of research is in its fledgling stages. Integration of a protective factor focus into RNR-based programming has largely been absent from the research literature. Further, it is unclear whether treatment planning using the SAPROF

would be superior to treatment plans generated from risk-based tools such as the Violence Risk Scale. Currently, the authors of the SAPROF have not produced guidelines detailing which treatments to implement in the presence or absence of certain protective factors. Importantly, the authors acknowledge in the administration manual that they plan to make continuous improvements and revisions to the SAPROF.

Additionally, some researchers argue that the inclusion of protective factor tools in risk assessment may have other benefits beyond predictive accuracy. Such researchers have speculated that risk assessments based solely on risk factors could hypothetically lead to a negative connotation or bias in reports, thereby generating pessimism among clinicians and unbalanced final evaluations by parole boards. Potentially, this could lead to lengthier periods of detention. Although scant research exists examining these potential impacts of the risk-focused assessment, these hypothetical impacts would be costly to all parties involved.

Further, current research tends to have a narrow focus toward the overprediction of offending rather than evaluating other potentially positive community outcomes. Indeed, it makes logical sense that protective factors may be uniquely situated to provide accurate assessment of positive community outcomes (regardless of whether the offender reoffends) including returning to school, reduced hospitalizations, holding consistent employment, or maintaining safe and stable housing. One could argue that an offender who reoffended and had maintained stable employment and housing is more successful than an offender who reoffended and was unable to attain employment or safe housing. Again, scant research exists in this area, but this could represent a unique research avenue in the burgeoning forensic positive psychology literature.

Final Thoughts

The SAPROF represents an important addition to the risk assessment literature and is arguably one of the best developed protective factor tools currently published. Although many conceptual and research questions remain, this would be expected for any new risk assessment tool. Given the authors' stated commitment to continually

improve and revise the tool as new research is published, the SAPROF is a useful tool that may become valuable in forensic assessment.

STRUCTURED ASSESSMENT OF VIOLENCE RISK IN YOUTH (SAVRY)

The SAVRY is one of the most widely used and researched structured risk assessment tools designed to assess risk of general violence in male and female youth between the ages of 12–18 years. The SAVRY is particularly relevant to the topic of correctional psychology, given its applicability to the assessment and management of risk in adolescent offenders. The current entry describes the SAVRY and briefly discusses its purpose and development, then provides a broad overview of empirical findings regarding its reliability and validity.

Description and Purpose of the SAVRY

The SAVRY consists of 30 items (i.e., 24 risk factors; 6 protective factors) that are grouped into three risk domains, Historical Risk Factors, Social/Contextual Risk Factors, and Individual/Clinical Risk Factors, and one protective domain,

Protective Factors. Items are operationally defined within the SAVRY manual with the risk factors being rated as *low*, *moderate*, and *high*, whereas the protective factors are rated dichotomously as *present* or *absent*. However, given that the SAVRY is not an exhaustive list of risk/protective factors, an assessor may take into consideration other individual or situational factors (i.e., case-specific factors) that may contribute to or mitigate an adolescent's risk of violence (i.e., Additional Risk Factors/Additional Protective Factors). Moreover, an assessor may judge a risk or protective factor as being particularly salient with respect to a youth's level of violence risk and may, therefore, identify such factors as critical items. Table 1 lists the items of the SAVRY by domain.

The SAVRY is intended to be administered as part of a comprehensive forensic assessment, and scoring of the items takes approximately 10–15 min once information has been gathered. The overall purpose of the SAVRY is to help guide the assessment and management of violence risk. Given that adolescence is a time of rapid developmental change, the SAVRY was developed to account for the dynamic and contextual nature of adolescent violence, while also providing developmentally informed risk and protective factors (e.g., poor parental management). To increase its flexibility, the SAVRY adheres to the structured professional judgment approach to risk assessment in that a final score is not produced by summing the item ratings; rather the assessor, based on his or her consideration of the risk and protective factors and his or her own professional expertise, generates a final determination regarding the nature and severity of a youth's risk of future violence using a summary risk rating of low, moderate, or high. An additional summary risk rating can be made using the SAVRY regarding future risk of nonviolent offending due to the overlap between risk factors for violent and nonviolent offending. Although no final risk score is produced in practice, much of the research conducted with the SAVRY has used total scores derived by summing the risk factors to produce a risk total score and/or by summing the factors across the various domains. Whereas the likelihood for violent reoffending typically increases as a function of the number of risk factors present, not all youth who exhibit a wide range of risk factors are to be

Table 1 Structured Assessment of Violence Risk in Youth Risk and Protective Items by Domain

Historical Risk Factors

1. History of violence
2. History of nonviolent offending
3. Early initiation of violence
4. Past supervision/intervention failures
5. History of self-harm or suicide attempts
6. Exposure to violence in the home
7. Childhood history of maltreatment
8. Parental/caregiver criminality
9. Early caregiver disruption
10. Poor school achievement

Social/Contextual Risk Factors

11. Peer delinquency
12. Peer rejection
13. Stress and poor coping
14. Poor parental management
15. Lack of personal/social support
16. Community disorganization

Individual/Clinical Risk Factors

17. Negative attitudes
18. Risk-taking/impulsivity
19. Substance use difficulties
20. Anger management problems
21. Lack of empathy/remorse
22. Attention deficit/hyperactivity difficulties
23. Poor compliance
24. Low interest/commitment to school

Protective Factors

- P1. Prosocial involvement
 - P2. Strong social support
 - P3. Strong attachments and bonds
 - P4. Positive attitude toward intervention and authority
 - P5. Strong commitment to school
 - P6. Resilient personality traits
-

automatically considered high risk. This is due to the weighting of the SAVRY items being determined by the assessor based on their relevance to the individual case (i.e., the identification of

critical items). Lastly, while the SAVRY does include static (i.e., historical) risk factors, approximately two thirds of the risk factors are potentially dynamic (i.e., changeable), and the authors (Randy Borum, Patrick Bartel, and Adelle Forth) recommend that youth be reassessed at regular intervals particularly in situations in which transitional (e.g., transfer from custody to the community) and/or developmental changes are occurring, though no specific time frame has been provided.

Development of the SAVRY

Development of the SAVRY began in 2000, when Borum, Bartel, and Forth amalgamated items from two independently developed risk assessment tools still within the prototype stage. Item selection was primarily based on a review of the empirical literature on adolescent violence (i.e., through prior reviews, meta-analytic investigations, and individual studies) and the magnitude/robustness of each risk/protective factor's relationship with violence. While varying degrees of empirical support were found for all items included within the SAVRY, a small number of items were retained despite their lower association with violence due to their perceived clinical relevance (e.g., poor compliance). Moreover, due to the relative lack of empirical research on protective factors in youth at the time of development, the protective factors included within the SAVRY were considered preliminary. This is reflected in the altered rating format of present/absent and the smaller number of protective factors incorporated into the SAVRY relative to the number of risk factors.

The SAVRY has gone through various stages of development and revisions based on preliminary research and feedback from professionals in the field. The various iterations included a pilot version and Consultation Edition. The Consultation Edition was further revised to reflect changes to Item 21 (referred to as *Version 1.1*). Initially, the SAVRY required administration of the Psychopathy Checklist: Youth Version as part of rating Item 21 (formerly referred to as *Psychopathic Traits*); however, this requirement was dropped following the initial printing of the Consultation Edition. This was to reduce the risk of negative connotations associated with the term *psychopathy* and to ensure that rating of the SAVRY was not

dependent on the administration of another measure or tool and was in keeping with the intention of the measure to be used by professionals working with adolescents, not necessarily clinicians. Moreover, by revising the item to represent low empathy/remorse, the authors argued that capturing the cluster of traits represented by the item was more important than assessing the clinical construct of psychopathy as a whole. The SAVRY was subsequently published commercially through Psychological Assessment Resources in 2006.

Reliability and Validity of the SAVRY

A strong evidence base exists to support the reliability (i.e., internal consistency and interrater reliability) and validity of the SAVRY within both applied and research settings. Although less of a focus among risk assessment tools, the SAVRY has demonstrated adequate psychometric properties (e.g., internal consistency), while interrater agreement has typically ranged from good to excellent for the risk total score and summary risk rating. With respect to predictive validity, reviews, meta-analytic investigations, and independent studies have found moderate to large effect sizes for the SAVRY in predicting violent, nonviolent, and general (i.e., any) reoffending among adolescent offenders across various follow-up periods; however, results of studies examining the SAVRY's predictive validity among adolescent male sexual offenders have been mixed. Despite this, researchers have found the predictive validity of the SAVRY to be comparable across age (i.e., 13- to 15-year-olds vs. 16- to 18-year-olds), gender, type of sample/setting (e.g., specialized school, correctional, forensic/psychiatric, community, and treatment), study type (i.e., prospective/retrospective), and cultural and ethnic background (albeit research is limited in this regard). In addition, the SAVRY has been found to be equally predictive of institutional and community violence and, despite being significantly associated, to add incrementally to the prediction of recidivism relative to other common adolescent risk assessment tools such as the Youth Level of Service/Case Management Inventory. Although the protective factors of the SAVRY are considered underdeveloped relative to the risk factors, the Protective Factors domain has demonstrated negative associations with violence and general antisocial

behavior and, in some studies, has been found to add incrementally to the risk domains in predicting reoffending.

Given that approximately two thirds of the SAVRY items are purportedly dynamic in nature, recent research has examined whether the SAVRY could reliably capture change in a sample of adolescent male sexual offenders, all of whom had undergone a residential cognitive behavioral treatment program to reduce risk of sexual offending, and whether the observed change in risk and protective factors was related to changes in offending outcomes. Dynamic items found within the Social/Contextual and Individual/Clinical Risk Factors and the Protective Factors domains displayed statistically significant changes over the course of treatment with approximately 8.0–38.7% of the sample of 163 youth displaying reliable improvements in risk. However, neither the dynamic change scores nor the presence of reliable change on the SAVRY was significantly associated with reoffending (i.e., any, violent, and sexual) after controlling for baseline scores on the Historical Risk Factors domain. Therefore, while dynamic risk and protective factors incorporated into the SAVRY can reliably capture change over time, further research is required before any firm conclusions can be made regarding the association between change in dynamic risk factors on the SAVRY and reoffending.

Final Thoughts

Empirical evidence has established the SAVRY's ability to predict violent reoffending, providing strong support for its use when assessing risk of violence in adolescent offenders.

Moreover, with improved resource allocation being observed following implementation of the SAVRY, it may serve as a useful aid when making informed decisions concerning the management of violence risk. To further support this process, in 2014, a risk management toolkit for youth justice professionals that directly maps onto the SAVRY items, referred to as the *Adolescent Risk Reduction and Resilient Outcomes Work-Plan (ARROW)*, was developed. The ARROW was designed to assist in the development of case-management plans by providing evidence-based resources and a structured approach for

identifying appropriate risk management strategies aimed at reducing risk factors and bolstering protective factors that have been incorporated into the SAVRY. Although research on the ARROW is limited, the addition of the ARROW to the SAVRY allows for a unique combination that further structures and guides the risk assessment and risk management process.

STRUCTURED INTERVIEWS IN LAW ENFORCEMENT SELECTION PROCESS

Interviews are one tool among many used in various selection processes, including the law enforcement selection process. In general, the goal of a selection procedure is to select the best qualified individual for the job while minimizing potential errors in decisions made using these tools. One way to minimize the potential for decision errors related to interviews is to gain an understanding of the characteristics, development considerations, and evaluation processes associated with structured interviews. This entry discusses these aspects of structured interviews as well as employment law, with a focus on law enforcement.

Interview Characteristics

Levels of Structure

There are three levels of structure used during interviews. At one extreme is the structured interview that contains high levels of standardization and consistency and is designed to minimize question variation during an interview. At the opposite end is the unstructured interview that lacks standardization and consistency of questions asked during the interview process. Finally, combining both structured and unstructured interview

characteristics is the semi-structured interview. The appropriate level of structure used for an interview will vary depending on the goals of the interview. Additional information for unstructured and semi-structured interviews is provided herein, but the main focus is to explain the importance of structured interviews and provide guidelines to ensure high levels of standardization and consistency throughout the development process.

Unstructured and Semi-Structured Interviews

The traditional interview may be referred to as an unstructured interview. These interviews lack structure and consistency in that interviewers asked interviewees a variety of questions but do not ask every interviewee the same questions. Interviewers are also permitted to ask unscripted or follow-up questions related to applicants' or interviewees' responses. This process allows for an expansive amount of information to be collected from applicants and interviewees but prevents interviewers from making comparisons across interviewees because of the inconsistency of information collected.

A semi-structured interview is an interview containing questions that all interviewees answer but allows the interviewer to seek additional information from each interviewee by asking follow-up questions during the interview. Interviewers can compare interviewees' responses to questions asked of everyone but allows for interviewers to gather additional information to clarify interviewees' responses.

Structured Interviews

Structured interviews were created to improve the ambiguous and inconsistent unstructured interview. A structured interview is different from an unstructured interview in that it provides standardization and consistency as well as quantifies a qualitative evaluation process. With regard to employment hiring practices, structured interviews were developed to allow more accurate comparisons across job applicants as well as comparisons to current employees within jobs.

Structured interviews require that every interviewee receives identical questions in the same order and is evaluated using the same evaluation process. Structured interviews are the most rigid in design and offer the greatest amount of

consistency across interviewees. The consistency of a structured interview is emphasized not only in the administrative process of the interview but also during the evaluation of responses.

Factors Impacting Standardization and Consistency

High levels of standardization and consistency are essential to maintaining structure during the interview process. Factors that may impact the standardization of a structured interview include the interview environment, order and delivery of questions, length of interviewees' responses, and documentation method of responses. The structured interview is designed to be rigid and controlled, but if other factors are not also controlled, then standardization and consistency of the process may be compromised.

Interview Environment

Controlling the interview environment is advised and considered good practice so all interviewees experience the same treatment. Lights, sounds, and talking should be minimized and controlled. For example, an interviewee who is interrupted by an alarm during an interview has a different experience from those who are not interrupted. Another example is when some interviewees complete the structured interview in a room with poor lighting and cool temperature and others do so in a room with bright lights and warm temperature. Differences in the interview environment can impact the standardization and consistency of the interview and make comparisons between and across interviewees inaccurate.

Order and Delivery of Questions

One way to ensure standardization of the structured interview is to ask the structured interview questions in the same order and with the same delivery for every interviewee. This includes wording of questions, pronunciation, annunciation, body language, and tone when asking interviewees questions. Minor changes between interviewees may result in a difference in interviewees' interpretation of the questions. One way to eliminate the potential variations between interviewees is to select one person to read the interview questions

using a script. This creates consistency in question wording as well as delivery across all interviewees.

When a large number of interviewees are participating in the structured interview process, standardization and consistency can be preserved by using video and/or audio recordings of the interviewer reading the questions. This ensures that there are no variations in wording of questions, pronunciation, annunciation, body language, and tone of voice. This level of consistency during structured interview administration is paramount to ensuring a successful structured interview process.

Interviewees' Responses

Other factors that can compromise the standardization of a structured interview are the length of the interviewees' responses to questions and the documentation of those responses. All interviewees should be afforded the same amount of time to respond to a question (e.g., 2 min). This standardization increases interviewees' perceived level of fairness because all interviewees received the same treatment during the structured interview.

How raters document responses is also important and may differ for live versus recorded evaluation of responses. For live structured interviews, evaluators must be diligent in documenting all relevant information during the interviewee's response. Margin for error in live structured interviews is low, and evaluators must accurately document all relevant information immediately. Another option is to have evaluators present during the live structured interview but also video/audio record responses for later review if needed. A third option involves having no evaluators present during the structured interview administration and video/audio record responses for evaluators to review at a later date.

Structured Interview Development

Certain factors should be considered when developing a structured interview: question relevance to the job (selection interviews), how many and what type of interview questions will be developed, and how the interviewees' responses will be evaluated. The different methods used to develop structured interview questions vary in complexity, but there are a few guidelines that all development methods should include.

Job Relevance

Structured interviews used for employment decisions should be developed using information about the job, which is gathered through a job analysis (i.e., a process that identifies the work behaviors and tasks performed on the job). This process also identifies knowledge, skills, and abilities an individual must possess in order to successfully perform the job. Questions used during a selection interview should be related to the target job.

Writing structured interview questions can be a difficult task if knowledgeable individuals are not consulted during the development process. When writing structured interview questions, individuals currently working in the job or their supervisors should be included to ensure that the content of the questions remains relevant to the job. Individuals developing structured interviews should collect data demonstrating that the structured interview questions are related to the target job.

Types of Structured Interview Questions

There are two types of structured interview questions: situational questions and past experience questions. Situational questions describe a situation or a scenario and then ask the interviewee to describe or explain what he or she would say or how he or she would handle the situation. This type of interview question is future focused. In other words, situational questions assume that the interviewee will describe how he or she would behave if he or she were really in the situation.

The second type of structured interview question relates to past experience. These questions simply ask the interviewee to provide examples of past experiences or training related to the question. For instance, if a structured interview question is written to evaluate interviewees' customer service abilities, the question may ask the interviewees to describe a past experience when they had to assist an angry customer. The interviewees would then provide one or more examples of past experiences dealing with angry customers. Given the premise that past behaviors predict future behaviors, interviewees are then evaluated based on the likelihood that they will be successful in handling similar situations in the future.

Evaluating Interviewees' Responses

A common method used to evaluate interviewees' responses to structured interview questions is to create examples of behavior called *benchmarks*. Benchmarks are examples of objective behaviors that interviewees exhibit or state during the structured interview process. Benchmarks are a commonly used form of evaluation for structured interviews because individuals knowledgeable about the job are able to develop objective examples of behavior. These examples of behavior are then used to categorize interviewees' responses as unacceptable, acceptable, or outstanding. The categories typically correspond to a numerical value that can be combined across all structured interview questions to create a score, thus creating a method of comparing all interviewees. This process of assigning numerical values to behavioral benchmarks quantifies an otherwise qualitative process.

Evaluating Structured Interviews

Evaluator Selection

Selecting individuals to evaluate or rate structured interview responses is an important process. It is critical that individuals selected to evaluate an interviewee's responses are knowledgeable about the job. For example, evaluating the structured interview responses of an individual in the law enforcement field may be difficult for someone who does not have experience or training within that same field. For certain jobs, like law enforcement, the evaluator's current rank (e.g., sergeant, lieutenant, captain) is also an important consideration. For example, when evaluating the structured interview responses of an applicant applying for a police sergeant job, individuals at the officer rank would not possess the experience and training needed to evaluate sergeant applicants' interview responses. When evaluating structured interview responses for law enforcement careers and similar rank-structured public safety careers, individuals selected as evaluators should be employed at that same rank or one rank higher. For instance, when testing for police sergeant, an assessor should have attained at minimum the rank of sergeant, but lieutenants may also be used.

Evaluation Process

An effective method for evaluating interviewees' responses to structured interview questions is to use panels that consist of two or more evaluators or raters. The raters should listen and observe the interviewees, then use the benchmarks to make ratings based on the interviewees' responses to each structured interview question. There are numerous options and practices used to combine ratings for multiple raters. One practice is to use a preliminary and final rating process that requires raters to reach an agreement on the final rating. Other practices simply average the ratings given by all raters. The specific rating process used may vary depending on the needs of the organization. Regardless of the exact rating process, it is important that all raters use the same benchmarks in the same manner to evaluate interviewees' responses. This ensures that the evaluation process is consistently applied across all interviewees.

Evaluator Training

An important step in increasing the consistency of the structured interview rating process and reducing the potential for errors is to train evaluators or raters on the rating process. Training raters how to use benchmarks and other evaluation processes improves the consistency of the scoring process as well as reduces errors. In addition, training ensures that each rater understands the rating process and how the benchmarks relate to each question. Consistency of the rating process is improved when raters are trained to follow basic guidelines and processes during the evaluation process. Specifically, training should emphasize the importance of rater objectivity when rating interviewees' responses. The training should discuss the benchmarks for each structured interview question as well as provide practice sessions for raters to evaluate interviewees' responses using the benchmarks.

Adequate rater training should teach raters to observe and record only relevant behaviors and to take detailed notes. General note taking and short hand or individualized note taking methods can be allowed, but providing practice sessions for raters to evaluate responses will help ensure that raters are observing and capturing the same behaviors for the same interviewees.

Rater training also provides the opportunity to educate raters about the types of rating errors commonly made by untrained raters. When untrained raters commit rating errors, it may lead to problems with consistency and perceived fairness of the entire evaluation process. Untrained raters may make the mistake of using feelings or personality traits to evaluate responses instead of maintaining objectivity. Raters should avoid making inferences or assumptions about what an interviewee is trying to articulate and instead remain objective by only evaluating what the interviewee states he or she would say and do. This is where audio and/or visual recordings of the interviewees' responses are useful. Recordings allow raters the opportunity to take breaks and listen to interviewees' responses multiple times to ensure objectivity. Recording responses also increases the level of detail in raters' documentation as well as confidence and consistency in evaluations.

Employment Law and Structured Interviews

There are several legal entities and laws designed to protect workers and job applicants in the hiring process. It is important that individuals involved with the hiring process have an understanding of the legal practices that organizations should implement when developing and administering structured interviews and other selection procedures. Law enforcement is an extremely litigious field as it relates to enforcing the law and dealing with the individual rights of suspects and those who have been arrested. The internal workings of law enforcement, as it relates to employment practices and employment law, have an equal if not greater presence in both active and closed U.S. court cases. Law enforcement administrators and human resources professionals should be vigilant in ensuring that hiring and promotional practices are legal.

It should be noted that agencies exist at the federal, state, and local levels. The main federal agencies that oversee employment law and staffing are the Equal Employment Opportunity Commission and the Department of Labor. The most common laws that apply to hiring are Title VII of the Civil Rights Act (1964, 1991), Age Discrimination in Employment Act (1967), Americans

with Disabilities Act (1990, 2008), Genetics Information Nondiscrimination Act (2008), and Uniformed Services Employment and Reemployment Rights Act (1994). Additionally, there are civil service laws that may apply to government entities that have requirements for staffing, which are different from those of private entities. Using properly designed and administered selection procedures such as structured interviews can minimize the possibility of an organization being named in a lawsuit brought by an interviewee.

Structured Interviews in Law Enforcement

Hiring and Promotions

There are several evaluative tools and tests to choose from when designing selection procedures for hiring and promotions within law enforcement. Given the level of public contact and concerns with public safety, it is increasingly important that police departments hire and promote their highest performing law enforcement professionals. In an effort to accomplish this, law enforcement organizations adopt extensive selection procedures that require applicants to complete multiple types of evaluation tools (e.g., multiple-choice test, structured interview, mental health assessment, background check). Regardless of the number of evaluation tools a law enforcement organization uses during the hiring or promotional process, structured interviews are frequently one of the primary tools used across all ranks.

Structured interviews are one of the most versatile tools available for hiring and promotional processes. They are frequently used by law enforcement agencies because structured interview questions can be developed to evaluate applicants' responses to a variety of situations. Structured interview questions can be designed to evaluate how police officers handled specific situations in the past as well as how they would react or behave during situations they have not yet experienced on the job. Structured interviews can be developed as the sole selection tool for hiring decisions, or they can be combined with other evaluation tools for a more comprehensive picture across applicants.

Structured interviews are preferable to other selection tools because they are easily developed and reduce the need for applicants to possess other

attributes unrelated to the job. For instance, multiple-choice tests typically require applicants to be able to read at a certain grade level. Applicants' scores on a multiple-choice test can be influenced by their reading proficiency. Structured interviews are able to focus solely on the aspects important to the job and minimize the potential for other factors influencing the applicants' ability to perform well.

Other Uses in Law Enforcement Environment

The adaptability and flexibility of a structured interview along with the consistency in evaluation is why structured interviews have become so widely used in various evaluation processes. Structured interviews are used not only for selection purposes but also to evaluate attitudes of individuals in numerous environments. A structured interview may be one of several tools used to make decisions about applicants, but when the structured interview is designed, administered, and evaluated properly, it can be the most informative tool utilized in law enforcement selection.

Structured interviews are also used in other law enforcement areas to gather information. Some examples include forensic interviewing of offenders, inmate interviews, and evaluating of police and correctional officers' attitudes toward offenders. Clearly the adaptability of structured interviews allows law enforcement agencies to use them for a multitude of organizational evaluation initiatives beyond selection decisions.

STRUCTURED RISK ASSESSMENT–FORENSIC VERSION (SRA-FV)

The SRA-FV is one of a number of tools that professionals may use to assist them in assessing an individual's risk of sexual reoffending. Professionals working with men who have been convicted of committing a sexual offense are commonly expected to identify psychological factors that are thought to predispose offenders to recidivism (i.e., further offending). Such judgments may contribute to two practical tasks: First, assessing the degree of risk for future sexual offending

presented by an individual, which has implications for the degree of resources that should be assigned to managing his risk, and second, such judgments can increase the effectiveness of treatment interventions by focusing on the psychological problems that are most relevant to this specific individual. Assessment of the kinds of factors contributing to an individual's risk depend on knowledge regarding which factors contribute to risk when present and on determining which of these factors apply to the individual being assessed. This entry defines sexual recidivism and its risk factors, then examines the SRA-FV, its validity, and how it compares to other, similar risk assessment tools.

Risk of Sexual Recidivism

Sexual recidivism refers to someone who has been convicted for committing a sex offense going on to commit further sex offenses despite having been punished for the earlier offense. Researchers study rates of detected sexual recidivism, usually defined in terms of new charges or convictions for sexual offenses. This is sometimes called *official recidivism*. Inevitably such rates underestimate rates of actual recidivism since some people will reoffend sexually without ever being detected. Risk of official recidivism can therefore be thought of as indexing risk of repeatedly engaging in the kinds of sexual offense that are more likely to be reported. Typically, about one in 10 persons with a history of sexual offending is detected sexually reoffending within 5 years of being released after being punished for an earlier offense.

Individuals who have been convicted for a sexual offense differ greatly in their risk of sexually recidivating. About 2% of men released from prison for nonsexual crimes go on to be convicted for *out of the blue* sexual offenses within 5 years of release. Some known sexual offenders present a risk that is at this level (i.e., 98% of them are not known to commit further sexual offenses). At the other extreme, some men with a history of being convicted for a sexual offense have official sexual recidivism rates above 50%. Risk assessment generally seeks to determine where any given individual falls between these two extremes.

Factors Contributing to Sexual Recidivism Risk

Psychological factors contributing to sexual recidivism can generally be classified into one of four domains. These are (1) offense-related sexual interests: sexual interests which are more easily satisfied through sexual offenses than through legal sexual behavior (e.g., sexual interest in young children); (2) pro-offending attitudes: beliefs that make it easier to rationalize committing sexual offenses (e.g., believing that young children enjoy sexual activity with adults); (3) dysfunctional relational style: includes both an aggressive relational style and an inadequate relational style, as well as difficulty making or sustaining emotionally close relationships; (4) dysfunctional self-management: includes various ways in which people have difficulty regulating their immediate impulses in the service of their longer term self-interests. The SRA framework holds that to be usefully predictive of sexual reoffending psychological measures need to effectively assess problems from at least three of these four domains. Various structured measures have been created that achieve this (e.g., STABLE-2007 and the Violence Risk Scale–Sex Offender Version [VRS-SO]).

The SRA-FV

The SRA-FV is one of the structured measures designed to provide a reasonably comprehensive measure of psychological risk factors for sexual recidivism. It has items from three of the four domains. The sexual interest domain is covered by ratings for Sexual Interest in Children, Sexualized Violence, and Sexual Preoccupation. The relational style domain is covered by ratings for emotional congruence with children, lack of emotionally intimate relationships with adults, callousness, and grievance thinking. The self-management domain is covered by ratings for lifestyle impulsivity, resistance to rules and supervision, and dysfunctional coping. Items are selected and scoring rules defined based on previous research using the SRA framework.

Reliability

The SRA-FV was tested in a sample of sexual offenders who had been assessed for potential civil commitment, subsequently released, and then

followed for at least 5 years to determine their sexual recidivism rates. Interrater reliability was 0.64 for a single rater and 0.78 for two raters. A moderate ability to predict sexual recidivism (area under curve = .73) was found, similar to that achieved by other instruments for predicting sexual recidivism. Results also indicated that combining it with prediction instruments that are based on prior criminal history and other demographic factors gave better prediction than could be achieved using either kind of instrument alone. For example, the area under curve for predicting sexual recidivism from a static actuarial instrument alone was about 0.68/0.69 but rose to 0.75 when the static instrument was combined with SRA-FV. This is similar to the kinds of results that have been achieved with other comprehensive measures of psychological risk factors.

In Comparison With Other Assessments

The SRA-FV differs from the STABLE-2007 and the VRS-SO in the primary context it was designed for. STABLE-2007 was originally designed to assist community supervision of sexual offenders, while the VRS-SO was designed for use in the context of intensive treatment for sexual offenders run in an institutional setting. In contrast, the SRA-FV was designed to be used in an institutional context where sexual offenders are being assessed to inform decisions about potential release and where they therefore may be particularly cautious about making disclosures that may count against them.

As compared to the STABLE-2007 since the SRA-FV is designed to be used in an institutional setting, it may be preferable when assessing someone in that kind of setting. Compared to the VRS-SO, the SRA-FV is simpler to score and depends less on the kind of detailed clinical observation of behavior that is obtained through sexual offender treatment. On the other hand, it is less suitable for use in the community, and unlike the VRS-SO, it does not contain a method of assessing change in response to treatment.

Final Thoughts

To date only a limited amount of research has been carried out assessing the predictive value of the SRA-FV. Instruments that classify risk based on past criminal history have been tested with many thousands of offenders, while psychological

instruments like the SRA-FV have mainly been tested with hundreds of offenders. Converging results from different psychological instruments, along with an awareness of the limitations of instruments based on criminal history, have encouraged practitioners to employ psychological instruments despite the limitations of the research on which they are based. Of particular concern is evidence that it can be difficult to score psychological instruments reliably. Consequently, it is particularly important for practitioners to be carefully trained in scoring such tools and where possible to cross-check their scores with a colleague.

SUBSTANCE ABUSE, UNTREATED MENTAL ILLNESS, AND CRIME

Criminal behavior is influenced by a number of individual and social-level risk factors. *Person-level* risk factors (e.g., addiction, mental illness,

trauma exposure, stress exposure) and *place-level* risk factors (e.g., concentrated social disadvantage, lack of employment opportunities) are often identified as intervention targets within forensic psychology treatment. Since the mid-1990s, many crime-reduction initiatives have specifically identified and targeted person-level risk factors, such as substance abuse and untreated mental illness, via interventions that include assisted outpatient treatment, mental health courts, and drug treatment courts. The level of one's risk of criminal behavior is often dependent upon a host of factors, including the severity and treatment of one's substance abuse and mental illness, the co-occurrence of these two conditions, and the combination of other risk factors. This entry focuses on risks of criminal justice system involvement, specifically substance abuse and untreated mental health conditions.

Substance Abuse

The Centers for Disease Control and Prevention consistently estimates that approximately 10% of persons of 12 years or older have used an illicit drug in the past month in the United States; approximately 2.5% have used a psychotherapeutic drug with no prescription in the past month. Epidemiological studies indicate that illicit drug use remains very common in the United States and typically begins during adolescence. Epidemiological surveys also indicate that approximately 2% of adults in the United States meet the criteria for a substance abuse disorder, while approximately 10% report a substance abuse disorder at any point in their lives. Marijuana is consistently found to be the most commonly used illicit substance (though in the United States, more local and state jurisdictions are beginning to legalize marijuana for recreational and/or medicinal use), followed by prescription drugs; alcohol is one of the most commonly abused legal substances in the United States. The majority of persons with substance abuse disorders do not receive treatment.

Clinically, substance abuse disorders generally include a cluster of cognitive, behavioral, and psychological symptoms. These symptoms indicate that an individual continues to use a substance despite significant substance-related problems. Such individuals may take a substance in larger amounts over a longer period than was originally intended, express a persistent desire to regulate

substance use but report multiple unsuccessful efforts to do so, spend a great deal of time trying to obtain a substance, and possess an intense craving for the substance. Substance abuse tends to also involve significant social impairment (e.g., difficulties fulfilling major obligations at school, work, or home) and engagement in risky behaviors, which may lead to involvement in physically hazardous situations and/or criminal acts. In fact, many persons are under the influence of drugs at the time of their criminal act.

Mental Illness

The National Institute of Mental Health estimates that approximately 20% of U.S. adults live with a diagnosable mental health condition each year. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, mental illness can be defined as a syndrome with clinically significant disturbances in cognition, emotion regulation, or behavior, which are reflective of a dysfunction in processes (e.g., psychological, biological, or developmental) underlying mental functioning. Moreover, mental illness is usually associated with significant distress or disruptions in social functioning or other important activities. Following a diagnosis, criteria for defining disorder severity may be used, along with descriptive features of symptomology and course (e.g., partial remission, full remission, recurrent). Mental health conditions can be further specified into a category of serious mental illness (SMI). SMIs—which generally include psychotic disorders, bipolar disorders, and treatment-refractory depressive disorders—have been defined as conditions that tend to persist over one's lifetime, require long-term treatment and/or hospitalization(s), and significantly interfere with one's daily living and functioning. Roughly 5–7% of the U.S. adult population (i.e., those 18 years of age and older) is estimated to have an SMI.

Untreated Mental Illness

Many persons with mental illness do not receive treatment. According to the Center for Behavioral Health Statistics and Quality, young adults aged 18–25 years were less likely to receive mental health treatment than any other age group during a year-long period that was studied (only 33.6% received treatment), with higher treatment rates

found for adults aged 26–49 years (44.2%) and adults 50 years or older (49.9%). Other long-term studies indicate that as few as 20% of individuals who need mental health treatment actually receive it. Barriers to treatment may include less access to services and health insurance, perceptions of public stigma toward mental illness, and self-stigma for seeking help. Moreover, even when one is receiving mental health treatment, there may be a lack of engagement in the form of nonadherence to treatment plans.

Co-Occurrence of Mental Illness and Substance Abuse

Mental illness is associated with an increased risk of substance abuse. A number of reasons may explain this co-occurrence, including using substances as a way to self-medicate psychiatric symptoms, and increase in risk of mental illness that can be caused by persistent substance use (e.g., persistent cannabis use has been found to be linked with psychosis risk). In general, substance abuse disorders are common among people with depressive disorders, anxiety disorders, and personality disorders. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, persons diagnosed with SMI's such as bipolar disorder and schizophrenia are significantly more likely to have a substance abuse disorder, such as alcohol use disorder and cannabis use disorder. It should also be noted that many individuals are polydrug users (i.e., individuals who fit criteria for one substance abuse disorder often fit the criteria for another disorder too). The majority of persons receiving forensic mental health services have co-occurring mental and substance abuse disorders, and persons with mental illness and substance abuse issues are also overrepresented in correctional settings.

Contributing Factors to Criminal Behavior

Many factors are associated with criminal behavior, including social disadvantage, low socioeconomic status and income inequality, unemployment, lower educational attainment, urbanicity, antisocial characteristics, prior criminal behavior, parental criminal behavior, and history of trauma and victimization. Substance abuse and mental illness are often studied as additional person-level

contributing factors to crime. Empirical research regarding how much substance abuse and untreated mental illness contribute to crime, independently and combined, has spurred significant debate and conflicting viewpoints in this area.

In terms of research methodology, it should be noted that studies in this area often operationalize *crime* in different ways (e.g., minor crimes, violent crimes, crimes/arrests in general, self-reported violence, recidivism). Additionally, studies may define mental illness and substance abuse differently (e.g., mental illness vs. more specific categories, such as SMI), and the severity or treatment of one's mental illness is not always documented. Moreover, some early studies did not disentangle mental illness (e.g., depression, schizophrenia) from substance abuse disorders and instead grouped all of these conditions together under a label *psychiatric disorders*. Other studies have solely focused on SMI, such as schizophrenia, when considering the relationship between mental illness and crime.

Overall, empirical research suggests that there is a link between mental illness, substance abuse, and crime; however, this apparent link is complicated by other causal factors, and many researchers are hesitant to conclude that either of these conditions *cause* crime. Multiple large-scale studies have been conducted to evaluate the net contribution of various risk factors for crime, including dispositional, social-contextual, life-historical, clinical, and treatment factors. Early studies found that the prevalence of violence among persons with mental illness was more than 5 times higher (11–13%) than persons with no disorder (2%); persons with substance abuse disorders were 12–16 times more likely to engage in violent behavior (24–34%) than persons with no disorder. More recent research suggests that persons with SMI are 3–4 times more likely to engage in violence than individuals without SMI.

Across research findings, it appears that substance abuse is more directly related to criminal behavior and that the relationship between mental illness and crime is more complex. Many individuals report being intoxicated at the time of their offense, for example. These reports are consistent with research studies, which show how psychoactive substances can alter mood, cognitions, and consciousness. Other individuals with substance abuse issues may simply commit crimes in order

to fund their drug habits. In terms of mental illness, generally the public is concerned that such individuals are unstable, unpredictable, and prone to violence, due to similarly perceived alterations in mood and cognition. However, this is not often the case, especially for those who are receiving treatment. Moreover, research indicates that crime that is committed by people with mental illness can be plausibly linked to psychiatric symptoms in only 20% of cases.

Substance Abuse and Other Mediators to Crime

In order to substantiate causal inferences among mental illness, substance abuse, and crime, research indicates that crime risk is particularly elevated in persons with a mental health or substance abuse disorder who are young, male, and of low socioeconomic status. In particular, early studies found that individuals who were younger, male, abusing substances, and of low socioeconomic status were most likely to be violent (i.e., assaultive behavior), regardless of a mental illness diagnosis. It should be noted that the comorbidity of substance abuse and mental illness significantly raises the risk of criminal behavior and recidivism. Longitudinal data have also shown that violence is particularly elevated for individuals with SMI with co-occurring substance abuse and/or dependence, a history of physical victimization, and parental criminal history. However, once current substance abuse and other factors are statistically controlled for, the relationship between mental illness and crime often becomes nonsignificant. That is, other factors, including substance abuse, often act as a mediator in this relationship. It appears that mental illness can exacerbate crime risk when other individual risk factors are already present, but mental illness is not as robust of a predictor on its own.

Untreated Mental Illness and Crime

Persons who are actively experiencing psychiatric symptoms and/or not in treatment do appear to be at a higher risk of crime, though this risk is limited to particular types of symptomology. Meta-analyses indicate that most acts of violence or general crime among young persons

with SMI (i.e., experiencing psychosis) occur prior to treatment. Other systematic reviews and meta-analyses have found that nonadherence to treatment (e.g., medication noncompliance, not attending therapy sessions) also raises the risk of criminal behavior among persons with mental illness. In fact, studies have concluded that a diagnosis of SMI may add little additional crime risk, especially if an individual is in remission or receiving treatment.

Individuals who are actively experiencing positive symptoms of psychotic disorders (e.g., unusual thoughts, bizarre behavior, delusions, hallucinations) tend to be at a higher risk of violence than others, even when controlling for prior substance abuse and antisocial characteristics. Command hallucinations and persecutory delusions are two specifically identified positive symptoms that have been linked to crime. Conversely, individuals who are actively experiencing negative symptoms (e.g., avolition, alogia, anhedonia, social withdrawal) of psychotic disorders have been found to be at a lower risk of violent crime, and the presence of negative symptoms has been found to moderate the impact of positive symptoms in individuals who are experiencing both forms of symptomology. Thus, some clusters of psychological symptoms may actually be protective to engaging in criminal behavior.

Final Thoughts

Persons living with mental illness and/or substance abuse constitute a significant minority of the population. Such individuals often do not receive adequate treatment, which may contribute to subsequent lapses in judgment and breaks from reality. As individual predictors of crime, substance abuse is more associated with criminal behavior than mental illness, though both conditions pose an elevated crime risk. For persons with mental illness, specific symptoms of psychosis, no treatment or nonadherence to treatment, comorbid substance abuse, and traumatic life experiences raise the risk of criminal behavior. Still, the vast majority of individuals living with these disorders are not violent and do not engage in criminal behavior, and public perceptions of crime and unpredictably among these individuals, particularly those living with mental illness, are not

commensurate with reality. In fact, persons living with mental illness are disproportionately more often victims of crime than perpetrators of crime. Overall, individuals with mental illness or substance abuse issues are a heterogeneous group, and various other risk factors must be taken into account to fully understand any connections to crime.

SUBSTANCE ABUSE AND CRIME, LINKAGES BETWEEN

Substance abuse is a widespread mental health concern in the United States. As of 2015, more than 20 million Americans over the age of 12 years met diagnostic criteria for substance abuse or dependence, and rates of substance abuse have risen since the 1990s. Furthermore, the prevalence rates of substance abuse are much higher among correctional populations, with a 75% lifetime prevalence of substance abuse among prison populations. The very high prevalence rate of substance abuse among criminal offenders highlights the strong link between substance abuse and crime. This entry describes the diagnostic conceptualizations of substance use disorders, then examines the relationship between substance use disorder (with a focus on alcohol and illicit drugs)

and crime, the effect of substance use on legal outcomes, and substance abuse treatment programs for offenders.

Substance Abuse and Dependence Become Substance Use Disorder

Diagnostic conceptualization of disorders related to substance use has recently evolved. In the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (1994), substance abuse and substance dependence were distinct disorders. A substance abuse diagnosis is characterized by the consistent and maladaptive use of a specific substance that leads to significant impairment and negative consequences. By contrast, substance dependence is a pattern of substance use causing increased tolerance, withdrawal symptoms, and/or compulsive substance consuming behaviors. A substance dependence diagnosis denotes chronic substance use and more debilitating symptoms and often requires formal treatment for full recovery. For both of these diagnoses, *substance* refers to alcohol, illegal drugs, medication, or any toxin that has the potential for abuse. The more recent *Fifth Edition of DSM-5* (2013) has merged the diagnoses of substance abuse and dependence, thereby creating a single diagnosis called *substance use disorder*. The diagnosis is specific to particular substances, and substance use diagnoses are classified as mild, moderate, or severe. This shift in terminology allows clinicians to be more specific in their diagnoses.

Although illegal drug use and alcohol use are strongly correlated, they have a different relationship with criminal behavior. Because alcohol is a legal substance, only particular alcohol-related events elicit legal consequences (e.g., driving while intoxicated, underage drinking). However, the possession or use of illicit drugs is a crime, which impacts the relationship between crime and substance abuse disorder. For this reason, alcohol and drug abuse are often discussed separately in the context of criminal behavior.

Alcohol Use and Crime

Alcohol use is a common factor in criminal activity among both offenders and victims. A number of

theories attempt to explain the link between alcohol use and crime. One is based on the pharmacological effects of alcohol, with a focus on alcohol's tendency to decrease inhibitions, impair cognitive processes, and increase aggressive behaviors. This theory applies both to perpetrators of crime who may act in a rash and aggressive manner when under the influence of alcohol and also to victims because being under the influence of alcohol increases an individual's vulnerability to being victimized. Another theory holds that the mere expectation of alcohol's effects may be enough to lead someone to act more aggressively. Other theories postulate that individuals may use alcohol as an excuse to engage in criminal behavior. Finally, individual characteristics may help to explain the relationship. For example, alcohol use and criminal behavior may both be behaviors that are driven by a risk-seeking lifestyle; rather than positing a causal relationship between criminal behavior and alcohol, this theory posits that both may be traced back to a particular personality trait.

A significant amount of empirical support has been generated for the pharmacological explanation of the link between alcohol use and behaviors related to criminal activity. A great deal of this research examined the effects of alcohol consumption on aggressive behavior. In such experiments, participants are given particular amounts of alcohol and then asked to engage in a task with opportunities for aggressive behavior. The amount of alcohol each participant consumes is then compared to the likelihood of responding aggressively. Taken together, these studies reveal that those who consumed alcohol were more likely to behave aggressively. Additionally, the relationship between alcohol consumption and aggression is stronger when larger amounts of alcohol are consumed. Although these studies provide evidence for a causal link between alcohol consumption and aggressive behavior in a laboratory setting, the extent to which these findings also apply to real-world instances of alcohol use and criminal behavior is uncertain.

Correlational research with correctional populations demonstrates a weak but consistent link between alcohol use and crime. This relationship exists for both acute alcohol use (i.e., intoxication just at time of offense) and chronic alcohol use (i.e., longer term use of alcohol). Research

suggests a stronger association between cases of domestic violence and chronic alcohol use, but significant relationships also exist between general violent offending and chronic alcohol use and between criminal offending and acute alcohol use.

Approximately one third of criminal offenders report using alcohol at the time of offense. Public-order offenders (i.e., those who commit offenses involving driving under the influence, public intoxication, weapon offenses, and other crimes that endanger the general public) are the most likely to have consumed alcohol before committing an offense, followed closely by violent offenders. Although such data provide insight regarding the link between alcohol use and crime, they do not account for the many other variables that may moderate or contribute to this relationship.

Taken as a whole, research suggests that alcohol use is a mild risk factor for criminal recidivism, and it is a weaker predictor for reoffending than drug use, parental substance abuse, and the combined use of alcohol and drugs. Substance abuse in general is an important variable to consider, but the specific type of substance is important, making consideration of drug use equally or more important than consideration of alcohol use.

Drug Use and Crime

The link between illicit drug use and criminal behavior is more direct because these substances are illegal, so drug possession is itself a criminal offense. However, there are several other types of offenses associated with drug use. First, acquisitive offenses (e.g., theft, robbery) may be committed for the purpose of obtaining money to buy drugs. Second, general offending may be more likely for individuals engaged in drug abuse because of opportunities or pressures arising while spending time in drug markets or associating with other users or suppliers. Third, drug use has a robust relationship to violent offending.

The relationship between drug abuse and crime is complex, and some have asserted that it is bidirectional. Specifically, some theories posit that drug use causes criminal behavior, while other theories hold that criminal behavior causes drug use or that a third variable causes both behaviors. Furthermore, it is possible that the relationship is spurious rather than causal. For example,

community disorganization could explain a broad context for both drug abuse and criminal behavior but not necessarily cause drug use or criminal behavior.

Although the exact nature of the relationship between drug use and crime is unclear, it is well established that drug use and criminal behavior are strongly connected. Drug users are 3–4 times more likely to commit a crime than individuals who do not use drugs, with crack cocaine users 6 times more likely to offend than individuals who do not use crack, heroine/opiate users 3 times more likely, and cocaine users are 2.5 times more likely to offend. This relationship appears to be consistent across several types of offenses. Although there is an association between recreational drugs (e.g., marijuana) and crime, this relationship is weaker than the relationship between harder drugs (e.g., cocaine, heroin) and offending.

Drug use and crime are more strongly correlated than alcohol use and criminal behavior. With respect to reoffending, there appears to be a moderate relationship between drug use and general recidivism and a slightly weaker association between drug use and violent recidivism. A large majority of offenders resume using drugs after they are released from incarceration, and individuals who resume using drugs are 2–4 times more likely to reoffend than those who remain abstinent.

Impact on Legal Outcomes

In addition to impacting offense and reoffense behavior, substance abuse may impact an individual's trajectory through the criminal justice system. First, long-term, heavy substance abuse may impact cognitive functioning even after the drug use is discontinued; deficits related to such use may impact functional capacities related to criminal justice involvement, including capacity to waive *Miranda* rights. Additionally, acute intoxication at time of arrest may lead to diminished ability to understand the *Miranda* warnings, potentially leading to an invalid waiver of those constitutional rights.

Substance abuse may also be related to criminal culpability (i.e., whether an individual may be held responsible, including being found guilty, for a crime). Criminal responsibility requires both

that a criminal act occur and that the offender had some level of intent to commit the act. Substance use at the time of offense may reduce an offender's ability to form the requisite intent required to be considered criminally culpable. Although the standards vary across jurisdictions, in at least some jurisdictions, individuals who were unable to form the intent required for an offense because of voluntary substance use are able to raise a defense of diminished capacity, arguing that their culpability is reduced because of the inability to form intent resulting from intoxication. Additionally, the effects of involuntary intoxication (i.e., an individual is coerced or tricked into consuming the substance, or a substance has an effect that was not anticipated based on past use) may be the basis for an insanity defense.

Substance abuse may also be relevant to sentencing. A history of substance abuse may be considered by a court as a factor weighing in favor of either a shorter or a longer sentence. Some courts may view substance abuse as an indicator of likely poor performance on probation because of the association between substance abuse and further offending, which may lead to a harsher sentence. Alternatively, a court may view substance abuse as a mitigating factor, with substance use seen as reducing the offender's criminal responsibility or as a target for treatment/rehabilitation. Additionally, substance use may impact the type of programming an offender is expected to complete as part of his or her sentence, and the offender may be ordered to complete treatment specific to substance abuse.

Treatments

Providing substance abuse treatment to incarcerated offenders may create an opportunity for marginalized populations to receive treatment that they might not receive otherwise. Given the evidence that substance use is a factor in predicting criminal recidivism, treatment is a crucial aspect in disrupting the revolving door of the criminal justice system. Unfortunately, only about one in 10 offenders with substance use problems receives appropriate treatment. Although limited resources in correctional settings create obstacles for providing such treatment, a wide variety of promising approaches have been developed for individuals

who abuse substances, including treatment approaches with established effectiveness with justice involved individuals.

Pharmacological approaches to treating substance abuse have proven to be somewhat effective. Antabuse, naltrexone, and acamprosate are medications commonly used to treat alcohol dependence. Antabuse disrupts the metabolism of alcohol, inducing nausea and vomiting when taken in combination with alcohol. To be effective, Antabuse must be taken daily, which may be problematic for those involved in the criminal justice system, either because of lifestyle instability interfering with regular medication use or because of intentional noncompliance. Nearly one third of individuals who are court ordered to take Antabuse deliberately do not take the medication as prescribed. For these types of medications to be effective in treating substance abuse, individuals must be motivated to change their drinking patterns and be willing to use medication to support them in achieving that goal.

Naltrexone and acamprosate are other medications used to treat alcohol abuse, and each primarily works by decreasing cravings for alcohol among those who have developed dependence. Both medications have proven to have significant but small effects in reducing drinking and remaining in treatment. Research suggests that while naltrexone is more effective in preventing excessive drinking, acamprosate was more effective in helping individuals abstain from alcohol. Naltrexone, acamprosate, and Antabuse all have potential side effects, and each interacts with other medications or health conditions, which may prevent the use of these medications with some individuals.

Pharmacological approaches have also been developed to treat drug abuse. Opioid maintenance is a pharmacological approach to treating drug abuse that reduces cravings, stabilizes drug levels, and increases willingness to engage in behavioral therapy. Several medications have been developed for this purpose, including methadone, naltrexone, buprenorphine, and levo-alpha-acetylmethadol. These medications work by replacing illegal, short-acting, highly neurochemically rewarding substances (i.e., heroin or illegally obtained prescription opiates) with legal, longer acting, less neurochemically rewarding substances. High doses of methadone appear to be most

effective in reducing drug use, eliciting the highest treatment retention rates of the opioid maintenance medications. Unfortunately, opioid maintenance programs conducted in correctional settings show mixed results in reducing recidivism. Some studies indicate that individuals involved in opioid maintenance programs may have higher recidivism rates than individuals not in opioid maintenance. This may be partially explained by the difficulty that offenders may face in accessing opioid maintenance therapy upon release from prison. Accordingly, the effectiveness of correctional opioid maintenance programs in reducing recidivism may be enhanced by continuity of care between incarceration and release.

The outcomes for pharmacological treatments for alcohol or drug abuse are typically enhanced when pharmacological therapy is paired with behavioral therapy. Cognitive behavioral therapy (CBT) is used to treat many types of mental health disorders and seeks to correct maladaptive thoughts to change behavior. For offenders who abuse substances, this type of therapy is helpful in promoting prosocial behavior. Variations of CBT offered throughout correctional facilities include reasoning and rehabilitation, moral reconnection therapy, and relapse prevention.

Relapse prevention is a specific form of CBT that has shown particularly promising outcomes in treating substance abuse. This intervention teaches participants to recognize high-risk settings and cues that may lead to substance use and to avoid or better manage such situations to reduce the likelihood of drug use. Research supports the efficacy of treatments involving relapse prevention strategies over other psychosocial interventions, revealing greater posttreatment abstinence levels than contingency management and CBT.

Motivational interviewing may be paired with any of the aforementioned CBT approaches to enhance readiness for change or to encourage individuals to more fully engage in treatment. Motivational interviewing is a counseling technique designed to help cultivate a therapist–client relationship and ease clients into the idea of therapy. The approach is intended to prepare clients for making behavioral changes by guiding the client to identify reasons for changing problematic behaviors. This method is especially appealing for individuals who are court ordered to treatment

because it uses a nonthreatening approach to engage clients in therapy and prepare them for a more formal form of substance abuse treatment. Motivational interviewing has been shown to increase treatment retention, improve motivation for recovery, and reduce recidivism among incarcerated populations.

Two other models, therapeutic communities (TCs) and drug courts, are approaches to treatment of substance abuse among offenders, which require distinct programming and consideration for offenders with substance abuse histories, removing them in some way from the general criminal justice system. First, TCs require distinct treatment of substance-abusing offenders at the incarceration stage. TCs are a form of treatment used in correctional settings that isolate residents from other members of the correctional community to facilitate a structured and supportive environment. TCs use a community-based model of treatment in which residents feel comfortable confronting and supporting one another to correct maladaptive habits, and all individuals housed in the TC are provided with intensive substance abuse treatment. TCs have been found to be one of the most effective forms of correctional-based treatment for offenders who abuse substances by reducing both drug use and recidivism. Drug courts separate drug-abusing offenders at the prosecution stage of criminal justice processing. Drug courts function by removing substance-abusing offenders from traditional court dockets, instead processing their cases in separate courts designed to provide case management and treatment for offenders with substance problems. Such courts allow for greater oversight in a noncorrectional setting, allowing offenders to receive treatment in the community while still being held accountable for treatment compliance. A substantial body of research on drug courts supports their effectiveness in reducing both substance use and recidivism.

Final Thoughts

In addition to the previously discussed approaches, all of which have been linked to positive outcomes (i.e., substance use reduction, recidivism reduction, or both) when used with justice involved populations, some treatments for substance-abusing offenders are linked to *increased* substance use or recidivism. For example, the *boot camp* and

scared straight models of offender intervention are generally not effective in reducing recidivism or substance use, and they may actually increase substance abuse. Accordingly, treatment selection of substance-abusing individuals with justice involvement or at risk of justice involvement should be based on the research literature.

SUBSTANCE USE TREATMENT FOR OFFENDERS WITH MENTAL DISORDERS

Individuals with both a mental disorder (e.g., mental illness, personality disorder, or learning/developmental disorder) and substance use problems (ranging from abuse to dependence) are often described as having a dual diagnosis. Such individuals are common in secure forensic settings (e.g., prisons, hospitals), with estimates ranging

from one third to two thirds of offenders with mental disorder (MDOs).

While not all MDOs may reach threshold for a diagnosis of substance dependence per se, the majority of individuals with a mental disorder who use drugs and alcohol can be argued to have noticeable consequences to their physical or mental health (e.g., HIV infection, increased rates of suicide, greater use of services, increased rates of relapse and readmission), their social functioning (e.g., increased homelessness, decreased compliance with treatment, poor self-care, reduced education, and occupational activities), and offending behaviors (e.g., increased acquisitive offending and violent behaviors).

Substance use among MDOs also contributes to a variety of management problems within secure forensic settings. For example, noncompliance with prescribed medications, interactions between prescribed and nonprescribed drugs, overdoses, adverse effects on mental state, drug dealing, intimidation, peer pressure and bullying, and increased rates of violent incidents, either between MDOs or between MDOs and staff. These increased risks may be the result of substance use exacerbating personality traits such as impulsiveness and aggression, substance use decreasing reasoning abilities, substance-induced economic hardship leading to crime, or substance use interfering with treatment compliance.

Consequently, it is important that addressing substance use among MDOs be considered a priority within any comprehensive treatment package offered. Moreover, as treatment within secure forensic settings is often lengthy in time, not addressing it can be argued to be a wasted long-term opportunity to achieve detoxification (if required), increase stability and insight, and prevent future relapse and associated consequences. Therefore, since the early 2000s, it has been proposed that substance use treatment for MDOs be integrated into existing secure forensic settings. In this entry, the development and components of such programs are discussed.

The Development of Substance Use Treatment Programs for MDOs

Integrating substance use treatment for MDOs into existing secure forensic settings reduces the likelihood that MDOs will disengage from

multiple treatment sources and ensures continuity of care, supervision, monitoring, and treatment. There is some evidence for the success of such integrated approaches in reducing rates of hospitalization, symptoms, and substance use and increasing retention in treatment, although to date sample sizes remain small and there is little clear evidence that supports an advantage of one specific treatment program over another.

Within secure forensic settings, treatments have generally been slow to develop, and by the late 2000s, many MDOs with substance use problems remained inadequately treated. This is less of an issue within prison or probation settings than in secure hospital settings, as the former criminal justice services have developed a wider variety of accredited substance use treatment programs. However, these prison- or probation-based programs tend to focus more on offenders without a mental disorder and, consequently, do not explicitly consider the links and consequences between substance use and mental disorder. In addition, many MDOs are unable to access these programs as they tend to be longer in duration, which can pose challenges in concentration or attention for those with a mental disorder, and focus on *harder* or more significant drugs such as stimulants or opiates, whereas the evidence suggests that MDOs prefer to use alcohol and cannabis, traditionally considered less problematic or socially acceptable substances of abuse.

Since the late 2000s, specific treatment programs for MDOs have been developed and researched across a wider range of secure forensic settings (e.g., high-, medium-, or low-security hospitals and prisons). For example, work by Helen Miles and colleagues in the United Kingdom within low- and medium-secure hospital settings has shown initial promise in terms of their effectiveness, particularly in reduced substance use and self-reported cravings for use, improved adaptive attitudes toward substance use, increased confidence to make and maintain change, and good participant satisfaction with and improved engagement in treatment programs.

It has, however, been difficult to evaluate such programs using standard research methodologies, due to ethical difficulties in withholding treatment for control groups within randomized control trials, the small samples often available for

treatment, the time intensity of any treatment programs offered, the high attribution and relapse rates common in this population, and the need for follow-ups over many years to demonstrate the long-term efficacy of any treatment programs. In addition, it has been argued that detention in a forensic secure setting by itself can be enough for a significant minority of substance-using MDOs to become abstinent regardless of any substance use treatment offered because of the procedural and relational security of such settings (e.g., reduced access and availability of substances, regular drug screens and alcohol tests, regular room searches, and restrictions on movement and activities if found to be using substances).

There also remains a lack of research into understanding the link between substance use, mental illness, and offending behavior. For example, are substances having a *direct* effect on offending behavior (e.g., by causing an individual to be intoxicated and therefore disinhibited, resulting in an offence being more likely) or an *indirect* effect (e.g., the use of a substance by an individual has an impact on his or her mental disorder, thereby increasing symptoms such as paranoia or hallucinations, which in turn increase the individual's risk of offending behaviors)?

Consequently, although there is cause for optimism with regard to the limited research evidence about specific substance use treatment programs for MDOs, there is an ongoing need for professionals in this area to undertake formal research evaluations of such treatment in the future to advance the understanding of *what works* and *why* in the treatment of substance use among individuals with a mental disorder and offending behaviors.

Components of Substance Use Treatment for MDOs

Successful substance use treatment for MDOs has been suggested to require a long-term, graded or stepped approach that considers what current *stage* an individuals' motivation for changing his or her substance use behaviors is at. It should also be culturally sensitive and consider the specific types of substance use that an individual MDO has engaged in. Therefore, it is appropriate that there are geographical variations to programs that consider the individual needs of the participants.

Nevertheless, universal components of treatment that are effective with substance abusers (whether an offending or mentally ill population) appear to involve motivational enhancement approaches, self-monitoring, goal setting, interpersonal skills, developing social relationships, relapse prevention, and lifestyle modification, such as increasing occupational and leisure activities to reduce boredom. Psychoeducational approaches about drugs and alcohol are noted to be important but only if part of a comprehensive cognitive behavioral skills-based program. However, any psychoeducation should consider both legal substances (e.g., alcohol, prescription medications) and illegal substances (e.g., cannabis, stimulants, hallucinogens, opiates), ensuring that it is the negative impact of a substance upon an individual MDO that is addressed rather than the legal classification of a substance per se.

Programs should also be facilitated by a variety of professionals (e.g., medical doctors, psychologists, nurses, occupational therapists, social workers, prison or probation staff), so that a broad range of perspectives can be brought to treatment. However, all staff involved in facilitating substance use treatment programs should have training in working with the target population, skills in motivational interviewing and group work, and a working knowledge of different substances and their impact on mental health and offending behaviors. Regular staff training and supervision are also recommended.

Any successful programs cannot rely on just taking a parental, moral, or authoritarian view about substances with the MDO and avoid telling the individual to *just say no* to substances in the future. Such an approach is unlikely to result in meaningful intrinsic motivation to change or engagement in treatment. Instead, a longer term process of initial engagement and establishment of a therapeutic alliance, followed by collaborative persuasion or working toward change by highlighting the advantages to the MDO, then active psychoeducation or skills-based treatment, and relapse prevention will be more likely to result in a positive outcome.

Substance use treatment programs also need to be relevant to those attending them so may need to be adapted in focus, depending on the primary substance abuse of participants (e.g., alcohol vs.

drugs). Further modifications to ensure that attendees can benefit from treatment should also be considered when working with specific populations (e.g., those with ongoing acute psychotic symptoms or a learning disability). For example, group handouts could be simplified to ensure comprehension, and/or sessions could be more frequent to ensure that concentration and attention are maintained. Moreover, some research suggests that gender-specific adaptations to substance use treatment are warranted, with a particular focus on mood regulation, self-harming behaviors, and relationship issues when working with female MDOs.

Treatment programs that operate on a group format (to allow for peer challenge as well as mutual support) and are well structured, with a mix of didactic and reflective discussion elements, and the use of a variety of multimedia (e.g., videos) and activities (e.g., creative activities, opportunities to build skills through role-play) are more successful. Further elements that improve outcomes include a focus on building skills (e.g., assertive refusal skills, alternative activities to substance use such as education or occupation, goal setting, daily living skills), improving self-esteem and coping or problem-solving skills, and increasing personal responsibility for behavior.

It is often the case that individuals may need to attend treatment programs several times and repeat aspects if they lapse before they can achieve abstinence and a shift in their attitudes toward substances. Treatment may also need to be ongoing and involve a supportive element to maintain motivation for change in substance use throughout long periods of incarceration in secure forensic settings. It is helpful to also offer further support when increasing exposure to the community is allowed and an individuals' craving or desire, as well as opportunity for substance use, may return, as well as postrelease aftercare to reduce the risk of relapse. Treatment should also consider enlisting legal restrictions (e.g., probation orders, mental health restriction orders) as therapeutic allies, encouraging compliance with treatment (at least initially) to avoid sanctions such as reduced leave or recall to secure forensic settings.

Substance use treatment programs also involve individual assessments of MDOs' progress. Measures of outcome include standardized measures

of actual substance use (e.g., self-report questionnaires, objective measures of use such as drug or alcohol screens), changes in substance use attitudes or beliefs, and motivation for change. Other secondary measures of mood, problem-solving skills, or self-esteem can also be useful, as can subjective measures of satisfaction with treatment.

SUBSTANCE-ABUSING OFFENDERS

The concept of substance-abusing individuals in the justice system varies depending on the research study and different definitions that are used. Often the term *substance-abusing offenders* refers to individuals with substance use behaviors (i.e., using illicit substances and/or consuming alcohol) that influence offending (i.e., causation for criminal behavior), while others assume that those engaged in criminal behavior use substance abuse as part of their lifestyle (i.e., nondirective influence). Since the drug-crime nexus is very convoluted, it is unclear how substance abuse affects criminal behavior or even how involvement in criminal behavior affects substance use. This entry provides an overview of the concept behind substance-abusing justice involved individuals including a discussion of the criteria for diagnosing substance abuse disorder and the prevalence of substance use disorders in the general population and in the justice system. Finally, this entry examines the relationship between mental illness and drug use.

Overview

Goldstein's tripartite theory identifies three types of individuals with substance abuse disorder: those with psychopharmacological influences where drugs influence behavior, those who are involved in the business of drugs either for personal use or for monetary gain, and those who are affected by the surrounding environment where drugs are prevalent. While this theory is well-recognized, it suffers from a lack of evidence to indicate a causality between substance use and criminal behavior. To that end, there is a need to identify a typology of substance abusers deriving from theory and empirical knowledge about the relationship between substance abuse and criminal behavior. This typology is needed to ensure that the tautology (i.e., some substances are illicit and therefore this is criminal conduct) does not prevail in defining justice involved individuals with substance abuse issues, but rather the focus is the relationship between the substance use and criminal conduct. According to the Federal Bureau of Investigation (2010), these

substance abuse–related crime categories still account for the majority of arrests: 1.6 million arrests for possession of illicit substances and 1.4 million for driving under the influence.

In the criminal justice system, part of the problem is a lack of clear definition as to what is a substance abuser or substance abusing offender. Often the offense the person is arrested for is used as a proxy for the type of substance abuser. That is, an individual who is arrested for possession of drugs may be considered a substance abuser. But the individual arrested for a property offense (even if the goal was to obtain funds for drugs) is not considered a drug offender. Other means of identifying drug offenders is to use a standardized risk and need assessment tool that identifies those who use drugs. It is presumed that the use of substances is linked to criminal behavior. This is in contrast to the clinical definition provided by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Substance use is part of a continuum with an increasing number of symptoms (from an identified list of 11 symptoms) to qualify as a substance use disorder. If an individual has greater than six symptoms, then they are considered to have a serious substance use disorder. Moderate substance use disorders are in the 4–6 range.

The severity of the substance abuse does not consider the type of drug of choice or whether it is alcohol or an illicit substance.

Nature of Substance Use Disorders in the General Population and Arrestees

Two major surveys are useful to identify the unique characteristics of individuals who abuse substances among the criminal justice and general population. This distinction is important because it helps assess the degree to which the justice involved substance abuser is similar to or different from the general population. The National Household Survey on Drug Use and Health is an annual survey of 67,000 individuals to monitor the use of illicit substances and health status in the general population; using sampling weights, these statistics are useful for generating national estimates among the general population. This survey has two questions regarding criminal justice status:

One about whether the person was arrested in the last year and one about whether the person was on probation or parole in the last year. The second source of data is the Arrestee Drug Abuse Monitoring System (ADAM-II), a survey of arrestees in five counties—Atlanta, GA (Fulton County); Chicago, IL (Cook County); Denver, CO (Denver County); New York, NY (Borough of Manhattan); and Sacramento, CA (Sacramento County)—including an interview and collection of biological data. It provides an assessment of the characteristics of those who use substances in the justice population. This is in contrast to individual studies which have smaller samples or dated surveys of justice involved populations.

In the 2016 National Household Survey on Drug Use and Health, 28.6 million individuals over 12 years of age report use of an illicit substance in the past 30 days. The majority, 24 million, used marijuana; use of a pain medication was the second highest category (3.3 million). Nearly 137 million report alcohol uses in the past month with 48% reporting binge drinking (i.e., 5 or more drinks on one occasion). About 12% of the individuals report that they are heavy drinkers. Substance use disorders affect 20.1 million people including alcohol (15 million) and drug disorders (7.4 million). Nearly 4 million individuals experience both alcohol and drug use disorders.

In the 2013 ADAM-II survey, arrestees continue to have high rates of substance use. At the time of the arrest, the following are the rates of individuals who reported the presence of at least one drug in their system: Atlanta (63%), Chicago (83%), Sacramento (83%), Denver (74%), and New York (71%). Some offenders had more than one drug in their system, including Atlanta (12%), Chicago (19%), Sacramento (50%), Denver (27%), and New York (22%). The offense for those arrested in these sites varies considerably, illustrating that offense is not necessarily useful in identifying the substance abuse population. In Atlanta, this was the breakdown of the offenses by those arrested: 17.7% violent offenses, 30.4% drug offenses, 24.3% property offenses, and 45.3% other offenses; in Chicago, 23.7% violent offenses, 50.1% drug offenses, 28.2% property offenses, and 17.3% other offenses; in Sacramento, 19.1% violent offenses, 48.1% drug offenses, 12.4%

property offenses, and 50.5% other offenses; in Denver, 24.2% violent offenses, 13.6% drug offenses, 14.4% property offenses, and 63.5% other offenses; and, in New York, 18.8% violent offenses, 31.2% drug offenses, 32.5% property offenses, and 32.6% other offenses.

Marijuana

According to the NHSDHU, of the 24 million marijuana users in the general population, 1.8 million are between the ages of 12 and 17 years (6.5% of the overall aged population), 6.8 million (20.8%) are between 18 and 25, and 13.5 million (7.2%) are older than 26. Around 25% or 4.0 million people using marijuana have a disorder based on the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Marijuana substance abusers are more likely to be 18–25 years old. Of these, 4.0 million, 584,000 (2.3%), 1.7 million (5%), and 1.7 million (.7%) are between 12 and 17, 18 and 25, and older than 26, respectively. The drug use among the general population is similar in that arrestees in the ADAM-II survey report were detected to use marijuana at high rates: Atlanta (34%), Chicago (52%), Sacramento (59%), Denver (48%), and New York (44%).

Heroin

Within the general population, 948,000 (.4%) people reported using heroin within the past year. The majority of the users were older than 26. Approximately 708,000 individuals in the general population have heroin use disorders with the majority being 26 years of age and older. In the ADAM II survey, three jurisdictions had higher percentages of heroin users: Atlanta, Denver, and Sacramento reported increased opiates/heroin use from 2000 to 2014. The rates were 2% in Atlanta, 4% in Denver, and 3% in Sacramento. New York and Chicago saw decreases during this 13-year period including a 36% reduction in 2000 to 14% in 2013 and 20% in 2000 to 8% in 2013, respectively.

Alcohol

Alcohol is the most frequently used substance in the general population and among arrestees.

For the general population, the National Household Survey on Drug Use and Health uses three categories to describe alcohol usage within the past month: alcohol use (i.e., having at least one drink), binge drinking (i.e., having five or more drinks in one occasion, once), and heavy drinking (i.e., five or more drinks on one occasion more than once). Overall, 136.7 million (50.7%) used alcohol in the past month, 65.3 million (23%) reported being binge drinkers, and 16.3 million (6.0%) reported being heavy drinkers. Further, 43.6% of those who use alcohol are binge drinkers, 11.7% are heavy drinkers, and 26.8% are heavy drinkers. Among those who use alcohol, 2.3 million (9.2%) are between the ages of 12 and 17, 19.8 million (57.1%) are between 18 and 25, and 114.7 million (54.6%) are older than 26 years of age. Of binge drinkers, 1.7 million (4.9% of the overall aged population) are between the ages of 12 and 17, 13.3 million (36.4%) are between 18 and 25, and 50.9 million (24.2%) are older than 26 years of age. Lastly, for heavy drinkers, 191,000 (1%) are between the ages of 12 and 17, 3.5 million (10.1%) are between 18 and 25, and 12.6 million (6%) are older than 26 years of age.

The ADAM-II survey does not examine alcohol use among arrestees. But the 2004 National Bureau of Justice Statistics' Survey of Inmates in State and Federal Correctional Facilities found that 32.6% and 18.5% of state and federal prisoners, respectively, reported using alcohol at the time of their offense. Alcohol use was reported for 36.8% of violent offenses, 29.1% of property offenses, 21.4% of drug offenses, 41.2% of public order offenses, and 41% of other offenses for state prisoners. For federal offenders, alcohol use varied with 20.8% for violent offenses, 12.8% for property offenses, 18.5% for drug offenses, 18.3% for public order offenses, and 20.6% for other offenses.

Cocaine

In the general population, 1.9 million (.6%) people report use of cocaine and 432,000 (.1%) report use of crack in the past month. The majority of users were over 26 years old (this includes both cocaine and crack users). Additionally, 867,000 of those who use have a diagnosable cocaine use disorder, with the majority being over

26 years old. The use of cocaine among arrestees is the second most common drug detected in the ADMA-II survey: Atlanta (33%), Chicago (25%), Sacramento (7%), Denver (20%), and New York (33%). Crack seems to make up a higher percentage of the cocaine using arrestee population than powder cocaine with 14% (Atlanta), 8% (Chicago), 3% (Sacramento), 9% (Denver), and 15% (New York) using crack, while 5% (Atlanta), 6% (Chicago), 3% (Sacramento), 7% (Denver), and 5% (New York) using cocaine.

Drug Use and Mental Illness

According to the NSHDIH survey, 44.7 million (16.1%) people over the age of 18 had some type of mental illness but 10.1 million (~4%) had a serious mental illness within the past year. Mental illness affects those who are younger more so than their older counterparts, with higher rates among those ages 18–49. Comparatively, in the ADAM-II sample, only 2.3% had a mental illness within the last month in Atlanta, 5.8% in Chicago, 4.4% in Sacramento, 1.5% in Denver, and 4.7% in New York (these statistics were measured by the percentage of arrestees who were treated in a mental health/psychiatric treatment facility). Among the general population, 7.9 million people have both a mental health disorder and a substance abuse disorder, making up 39.1% of the population with substance abuse disorder and 16.2% of the population with mental illness. The ADAM-II survey does not directly measure comorbidity.

Substance Abusers in the Justice System

The justice involved population has a 4 times greater rate of substance abuse than the general population. As documented by Trevor Bennett, Katy Holloway, and David Farrington in 2008, a meta-analysis of 30 studies on substance use and recidivism assessed the differential outcomes reported in studies that explored recidivism based on drug of choice, with the odds of offending 6 times greater for individuals who used crack (odds ratio [OR] = 6.09) than those who did not, about 3 times greater for those who used heroin (OR = 3.08) as opposed to those who did not, about 2.5 times greater for individuals who used cocaine (OR = 2.56) than those who did not, and about 1.5 times greater for individuals who

used marijuana (OR = 1.46) than those who did not. Drug of choice is an important factor in an individual's further involvement in the justice system. Few studies, including national surveys, define substance abuse disorders according to a clinical disorder. Nor do the studies indicate how comorbid conditions may affect offending behaviors. While individuals involved in the justice system have higher rates of substance abuse than the general population, the relationship between drugs and alcohol and criminal conduct is still poorly understood.

SUICIDAL VERSUS NONSUICIDAL SELF-INJURY IN CORRECTIONS

Self-injury encompasses behaviors that result in deliberate harm or injury to oneself. This comprises a number of behaviors including nonsuicidal self-injury (NSSI), suicidal self-injury, and suicide attempts resulting in death. This entry focuses on and distinguishes between two forms of self-injury: suicidal and nonsuicidal.

NSSI includes self-directed behaviors that are deliberately inflicted and that result in injury or harm. These behaviors must be outside the realm of socially sanctioned forms of self-injury, which have a creative or expressive purpose such as piercings and tattoos. They must also be distinguished from suicidal self-injury in which one engages with specific intent to end one's life. The key difference between these two forms of self-injury is intent; NSSI occurs *without* specific intent to die, whereas in suicidal self-injury, this intent is present.

Self-injury, both suicidal and nonsuicidal, is common in correctional settings (nearly all U.S. state prisons report housing at least one offender who engages in self-injury) and, compared to the general population, is consistently found to be more prevalent among correctional populations. Such behaviors have important implications for offenders, the correctional rehabilitation environment, and institutional staff. This entry focuses on prevalence and description of the phenomena, risk factors, motivations and theoretical explanations, implications, and treatment.

Prevalence of Suicidal Self-Injury and NSSI in Correctional Settings

Prevalence rate estimates of self-injury among offenders vary because specific intent to die (or lack thereof) is not always recorded or established. Lifetime prevalence of NSSI among offenders is estimated to be up to 48%, and rates among offenders with mental disorders are even higher, with rates of NSSI up to 60%. It is estimated that between 2% and 18% of male offenders, and 5–24% of female offenders, will engage in some form of self-injury *during* their incarceration.

Prevalence rates of suicide attempts in offender populations are reported to range from 15% to 22%. These estimates are considerably higher than the general adult population, where 4% are estimated to have ever engaged in NSSI and nearly 5% report ever attempting suicide.

Suicidal self-injury and NSSI can also be differentiated in their methods and their lethality. The most common methods of suicide attempt in Western nations are hanging and ingestion of toxic substances, with the exception of the United States where use of firearms is predominant. In contrast, cutting is the most common form of NSSI, usually performed on parts of the body associated with low lethality such as forearms. Other common forms of NSSI include burning, scratching, head banging, and ligatures. The most common forms of NSSI in correctional settings are cutting, scratching, head banging, opening old wounds (also known as *interference* with wound healing), and inserting objects.

Gender Considerations

It is often assumed that NSSI is more common in women, yet epidemiological studies in the general population do not find differing rates of the behavior among genders. The same is true of borderline personality disorder (BPD), for which self-injury is a diagnostic criteria. That is, although BPD is generally thought of as being more common in women, and indeed is more likely to be diagnosed in women, when random samples of both genders are assessed for BPD, no gender differences are found. There are a number of reasons why these perceived gender differences may exist. For example, women may be more likely to disclose their self-injury, or health professionals may be more likely to directly inquire about self-injury with women. Alternatively, men may find it easier to provide plausible alternative explanations for their injuries given that men more commonly engage in activities or employment where injury is likely (e.g., construction) or to be involved in physical altercations.

In correctional settings, as with the general population, although women offenders have been the subject of more empirical research than have men, it is now commonly thought that self-injury is prevalent in male offenders as well. Gender

differences have been noted in methods of self-injury, however, with women being more likely to cut themselves and men being more likely to hit or burn themselves.

Risk Factors

NSSI and suicide attempts are correlated. Of individuals in the general population who engage in NSSI, one half to three quarters have also attempted suicide at least once, and 50% of individuals who attempt suicide have a history of NSSI. NSSI is one of the strongest predictors of suicide attempts and completed suicides. Among offenders, those who die by suicide are more likely to have a history of NSSI than other members of the offender population, and male offenders who engage in self-injury have higher levels of suicidal ideation than those who do not have such a history. NSSI is also a strong predictor of suicide both while incarcerated and after release.

Limited research has attempted to differentiate between these two behaviors in correctional settings, as it is often difficult to distinguish between self-injury that is motivated by an intent to die and self-injury that is not, and most correctional institutions respond to the behaviors in the same manner, regardless of intent. However, offenders who have made suicide attempts have been found to have different clinical presentations and histories than those who engaged in NSSI, so precise investigation and distinction is warranted.

Research has begun to focus on specific risk factors for NSSI in offender populations. BPD, trauma history (particularly sexual abuse), anxiety and depression, post-traumatic stress disorder, substance use, eating disorders, and aggression/impulsivity all have been noted as correlates of NSSI. Risk factors for self-injury with suicidal intent differ slightly, with depression (particularly hopelessness) being one of the most important risk factors for suicide attempts. Older age is also more strongly associated with suicidal self-injury than NSSI.

It is extremely likely that offenders who engage in NSSI while incarcerated have a history of doing so prior to entering a correctional setting. The majority of offenders who have engaged in self-injury (suicidal or otherwise) report initiating the behavior in adolescence, prior to any form of incarceration. This finding is also consistent with

the average age of initiation of self-injury, which is generally during adolescence. As such, it is highly plausible that risk factors for criminal behavior, substance use, or other antisocial behaviors will overlap with risk factors for self-injury, making the likelihood of self-injury in incarcerated populations that much greater.

Motivations and Theoretical Models

Historically, self-injury was viewed in correctional settings as a form of manipulation or as an attention-seeking behavior. Current research, however, suggests a more complex range of motivations for the behavior. NSSI has been theorized as serving a multitude of functions including affect regulation (i.e., emotional release), anti-dissociation, anti-suicide, interpersonal influence, self-punishment, and sensation seeking. While there is much evidence to suggest that NSSI serves multiple purposes, affect regulation has received the most empirical support in offender and nonoffender populations alike. Even when multiple motivations for the behavior are reported, emotional regulation is most frequently cited as a primary motivator. This finding is consistent in forensic populations. In correctional settings, affect regulation is the most commonly reported motivation for NSSI in both male and female offender population. Self-injury, in this case, serves as a coping mechanism that allows an offender to relieve distress and regulate emotional arousal. This is further supported by findings that negative emotions are the most commonly reported emotions prior to engaging in self-injury.

Self-punishment and self-directed anger have also received considerable attention as motivators for self-injury, as this function is commonly cited as a secondary motivation for self-injury. This function has been hypothesized as a manifestation of being raised in an invalidating environment, particularly among individuals with BPD, which is expressed as self-derogation or self-invalidation through self-injury, and often conceptualized as a stereotypically female motivation. Consistent with this theory, anger is frequently cited as a precipitating emotion to NSSI among offender populations.

Despite the convergence of evidence that self-injury serves primarily as a means of affect regulation, social influence and coercion as motivations

have also been documented in correctional settings. Reasons commonly cited include communication of distress or a desire to obtain external rewards (e.g., movement in or out of segregation, relocation to a psychiatric or medical unit). The social influence function is more common in offender populations than in the general (nonincarcerated) population, with such motivations often explicitly reported, particularly among male offenders.

Theoretical functional models of self-injury have been proposed in an attempt to account for primary motivators for the behavior. In particular, the Four Function Model, developed by Matthew K. Nock and Mitchell J. Prinstein, is notable because as of 2018, it is the only functional model of NSSI that has been validated with an offender population. Four Function Model is a functional approach to classification where functions of NSSI are categorized dichotomously: Behavioral reinforcements are either positive (addition of favorable stimuli) or negative (removal of aversive stimuli) and either automatic (intrapersonal) or social (interpersonal). For example, automatic negative reinforcement would occur when an individual uses NSSI to reduce negative emotions. Automatic positive reinforcement would occur when NSSI is used to create a desirable psychological/physiological state (e.g., dissociation, numbness). Desire to escape responsibilities and desire to obtain attention or material goods are examples of social negative reinforcement and social positive reinforcement, respectively. Research validating this model in correctional settings found support for all four functions, with automatic negative reinforcement being most strongly endorsed, followed by automatic positive reinforcement suggesting once again that emotional regulation is the primary function of NSSI.

Impact on the Correctional Environment

Working with offenders who self-injure can be extremely stressful for correction staff. The rates of burnout are elevated among staff working with any populations who engage in self-injury, and the correctional environment adds additional sources of stress. Staff who routinely engage with individuals who self-injure report significant anxiety, frustration, fear, anger, feelings of helplessness and inadequacy, and lower levels of job satisfaction. Most

staff report lack of knowledge and understanding of the behavior as well as lack of explicit training on how to effectively work with offenders who self-injure. Self-injury also presents significant costs to correctional institutions in terms of transfers from general prisons to specialized treatment centers and forensic hospitals. Appropriate treatment and prevention strategies are important for mitigating these impacts on the correctional system.

Intervention and Treatment

Institutional response to self-injury has often defaulted to the use of physical restraints or therapeutic seclusion (i.e., isolation, segregation). Research has found that these approaches have limited effectiveness and may in fact increase the frequency of NSSI and suicidal ideation. As a result, such approaches may place further burden on the correctional system, as segregation or hospitalization requires additional monitoring and intensive supervision. Evidence-based therapeutic responses are therefore recommended instead.

Dialectical behavior therapy (DBT) is a well-established treatment for NSSI and has received attention within the correctional literature. DBT was originally developed by Marsha Linehan to treat BPD and is frequently used to treat chronic self-injury, including NSSI and suicide attempts. DBT has been adapted for correctional setting in a number of jurisdictions across North America, the United Kingdom, and Australia and typically targets coping, self-monitoring, emotion regulation, distress tolerance, and interpersonal skills. DBT is a highly structured and intensive form of treatment that requires significant resources and training to implement. Other promising, less intensive interventions include problem-solving therapy, manual-assisted cognitive behavioral therapy, and START NOW, which is an intervention based on cognitive behavioral therapy and motivational interviewing that takes into account the realities of the correctional environment and is being implemented and evaluated in the United States.

SUICIDE AND SELF-HARM, LINKAGES TO VIOLENCE RISK

Suicide refers to the act of intentionally taking one's own life. *Self-harm* is the act of intentionally injuring oneself. Although self-harm, such as intentionally cutting oneself, can be associated with suicidal ideation, it is also known to

be an impulsive behavior used by many as a way of attempting to cope with emotional pain. The National Center for Injury Prevention and Control reported that, in 2013, suicide was the 10th leading cause of death in the United States for all ages. In 2103, there were over 40,000 suicides in the United States and more than 9 million adults reported having suicidal thoughts at some point during that same year. Suicide has been estimated to cost more than US\$50 billion in combined medical and work loss. Self-harm, such as cutting or burning oneself, has increased and hospitals are reporting an increase in the number of adolescents and young adults hospitalized for self-harm. This entry addresses the current understanding of suicide and self-harm and provides examples of both of these serious behaviors.

Typically, suicide and self-harm are considered acts of violence against oneself. For example, an individual who engages in self-mutilation is generally focused on self-harm and not likely to act out against others. Although this is also true for most people who commit suicide, there has been an increase in the number of people who commit violent acts against others and then commit suicide. In 1999, one of the deadliest high school shootings in the United States occurred in Columbine, CO, when two high school seniors planned an attack on their school and killed 12 students and a teacher and injured 21 others before committing suicide. Notes from the attackers found after the incident determined that from the outset, the two attackers planned to kill themselves to avoid being taken into custody. This tragic event led to an effort by the U.S. Department of Justice to fund research focused on developing a profile to identify characteristics of a typical school shooter with the hope that future tragedies could be avoided through early detection. Unfortunately, researchers had little success due to large variety of individual differences and motivations that were quite idiosyncratic.

Another similar phenomenon, referred to as a *murder-suicide*, involves the assailant killing another person then immediately thereafter committing suicide. Police officers are sometimes called to domestic disputes and, upon arrival, find that one spouse (usually the male)

has killed his or her spouse (and sometimes other family members), then taken his or her own life. These murder-suicides are generally unplanned and the perpetrator's suicide tends to be a reaction to guilt and shame following the murder.

Suicide by cop is a term developed by law enforcement officials to describe a phenomenon in which an individual purposefully plans to be killed by the police. This can involve an individual approaching the police aggressively, weapon in hand, and failing to obey police orders to drop his or her weapon. There have been other cases where an individual brandishes a fake gun or purposefully reaches into their pocket despite contradictory orders by the police, knowing that this behavior will lead to being shot. Suicide by cop is more common than many think, with estimates that as many as 10% of police shootings involve suicide by cop. This phenomenon presents a dilemma for police in that some police officers recognize when a person may be trying to commit suicide by cop and become trapped between their sense of empathy for the individual and their responsibility to protect themselves and others against the potential threat. If a police officer is forced to shoot and kill an individual committing suicide by cop, he or she is prone to additional stressors that are even greater than killing a typical armed assailant.

Since the 1990s, U.S. officials have encountered one of the most troubling linkages between suicide and violence. On September 11, 2001, 19 members of an Islamic terrorist group completed four coordinated suicide attacks in which four passenger airliners were hijacked at about the same time. Two of the aircraft were deliberately flown into the World Trade Center in New York City, one was flown into the Pentagon in Washington, DC, and the fourth was navigating toward the White House when it crashed into a field in Pennsylvania. These attacks killed almost 3,000 people and could not have occurred without the premeditated intent of suicide by all of the terrorists.

Although each of the scenarios listed above demonstrates a link between the commission of violence and subsequent suicide, the motivations to commit suicide differ for each scenario. Consequently, it is difficult to find a common correlate that links the two. For example, a person

who engages in suicide by cop may be motivated by a sense of having no way out of a situation, or perhaps has fantasies of dying a dramatic death. Terrorists who hijack a plane or strap explosives to themselves before blowing themselves up in the middle of a crowded area to kill as many people as possible may have a very different motivation.

As researchers try to get a better understanding of suicide's link to violence and risk, some have looked at violence and suicide from a different perspective. The question is if exposure to violence early in life increases one's risk for committing suicide. In most cases, it is difficult to determine why a person commits suicide. Even if individuals leave a suicide note describing a precipitating event or set of circumstances, it is hard to know what other factors (e.g., previous traumas, mental illness) played a role in their decision. Some research has found positive correlations between exposure to abuse and community violence and self-harm/suicidal behavior. It appears that, when looking at adolescents who engage in self-harm/suicidal behavior, it is more likely that these adolescents have experienced violence, such as being shot, stabbed, or attacked or witnessing someone else being shot, stabbed, or attacked.

SUICIDE AND SELF-HARM IN CORRECTIONS, RISK FACTORS FOR

Risk factors for suicide and self-harm among offenders are separated by offenders' location within the criminal justice system and include demographic and psychosocial correlates of suicide and self-harm. This is a topic of importance within criminal psychology because offenders are at greater risk of experiencing suicide-related distress and self-harm than the general population. For example, in the United States, there are 13 deaths by suicide per 100,000 individuals; however, there are 36 deaths by suicide per 100,000 individuals in detention facilities. That is, inmates are 2.77 times more likely to die by suicide than individuals in the general population. Therefore, suicide and self-harm are problems that offenders and forensic professionals are more likely to encounter. There have been many studies examining risk factors for suicide and self-harm in corrections. However, given that there are more males involved in corrections than females, research about suicide and self-harm has primarily been conducted using males. In addition, there is a greater amount of research about suicide in prisons, followed by jails and community corrections (e.g., probation and parole). Furthermore, self-harm has received less empirical attention than suicide among correctional populations. This is important to keep in mind when considering risk factors for suicide and self-harm in corrections. This entry provides an overview of risk factors for suicide and self-harm among offenders in prisons, jails, and community correction settings as well as a theoretical approach to suicide risk in corrections.

Suicide/death by suicide refers to death brought about by intentional self-injury with the intent to die as a result. *Suicide attempt* refers to nonfatal, intentional self-injury with the intent to die as a result. *Suicide ideation* refers to thoughts of ending one's own life. *Nonsuicidal self-injury* (NSSI) refers to intentional self-inflicted damage to one's body (e.g., cutting, burning, hitting) without intent to die. *Self-harm* is a broader term that does not specify intent to die during self-injury, and synonymous terms include *self-injury*, *self-injurious behaviors*, *parasuicide*, *undetermined*

suicide-related behaviors, among others. Suicide literature does not always delineate between self-injurious behaviors with versus without an intent to die. This has produced a body of research that is unclear as to which risk factors are associated with suicide attempts versus NSSI. This is important to keep in mind when considering risk factors for suicide attempts versus NSSI.

Risk Factors for Suicide in Prisons

The literature on prison suicide has focused on prisoner characteristics of individuals who die by suicide. For example, White prisoners are 3 times more likely to die by suicide than Black prisoners, and Hispanic prisoners are about 2 times more likely to die by suicide than Black prisoners. Contrary to findings that in the general population, males die by suicide at higher rates than females, and incarcerated males are no more likely to die by suicide than incarcerated females. Furthermore, prisoners charged with kidnapping have the highest suicide rate, followed by prisoners with murder charges, sexual assault charges, and assault charges. Violent prisoners are 2 times more likely to die by suicide than nonviolent prisoners. On the other hand, prisoners incarcerated for drug charges are the least likely to die by suicide. These characteristics may help identify those at elevated risk.

The prison environment may aid correction staff in identifying prisoners who may be more likely to die by suicide. Research suggests that 65% of deaths by suicide occur during the first year of incarceration; yet, time of day is not associated with death by suicide. Regarding housing location within prison, 80% occur when the prisoner is in their cell. Furthermore, 83% of suicides occur in maximum-security prisons and 23% occur in special housing units. However, prisoners who live in multiple occupancy cells (such as individuals at a lower security level) have lower rates of both suicide and homicide than those in single cells. The impact of segregation on mental health and suicide risk is a debated area in forensic psychology, such that some research suggests that segregation increases suicide risk, but other research shows no association between segregation and suicide risk. The association between housing location and suicide risk may be a function of the lack of positive social interactions,

which also appears to increase suicide risk among prisoners. For example, prisoners who lack connections with the outside world are at greater risk of a suicide attempt than prisoners who are more connected with the outside world.

Research has also examined prisoners' reasons for attempting suicide. Motivations for attempting suicide include inability to cope in prison, psychotic symptoms (i.e., hallucination and delusional thinking), an unexpected attempt (i.e., the prisoner did not expect to attempt), and attempts associated with withdrawal from drugs. Prison staff may have the perception that prisoners attempt or threaten suicide for a secondary gain (e.g., moving cells), which may lead to these attempts and threats not to be taken seriously. Despite the motivation, manipulative tendencies do not distinguish prisoners who made nonlethal attempts from those who made lethal attempts. Although perceived manipulative tendencies may play a role in inmates' behavior, the lethality of the attempt does not appear to provide insight into motives behind prisoners' suicide attempts. Therefore, all suicide-related behaviors should be treated seriously.

Risk Factors for Suicide in Jails

Research has provided demographic profiles of individuals who engage in suicidal behavior and self-harm; however, it is important to consider these demographic profiles within the context of demographic makeup of jails. The majority of prisoners who die by suicide are male, which may not be surprising given that there are many more males incarcerated than females. In addition, the majority of jailed suicide decedents are White and have an average age of 35 years (with approximately one third of these individuals falling between ages 33 and 42 years). Approximately 42% of suicide decedents are single, 19% are married, 9% are divorced, and the remaining individuals are separated, widowed, in common law marriages, or their relationship status is unidentified.

Furthermore, crime-related profiles may provide insight into suicide risk in jails. For example, approximately 43% of suicide decedents are charged with personal and/or violent offenses, 23% are charged with a minor crime (e.g., shoplifting, prostitution, traffic offences, violation of probation), 15% are charged with serious

property crimes (e.g., burglary, grand theft auto, grand larceny), and 19% are charged with alcohol and/or drug-related offenses. Further, approximately two thirds of suicide decedents have a prior criminal charge.

In addition to basic demographic information and criminal history, mental health information may also guide determination of suicide risk in jails. In the general population, the vast majority of deaths by suicide are associated with a mental health disorder; however, within jails, only about 38% of jailed suicide decedents have a mental health disorder (data were not available for about 30% of decedents). Furthermore, about half of suicide decedents have a history of drug abuse and only 20% are intoxicated at the time of their deaths. Similarly, a suicide attempt history is one of the strongest predictors of future suicide attempts and deaths; however, only about one third of jailed suicide decedents have a previous suicide attempt (data were not available for approximately 24% of decedents).

The jail environment may also increase distress among inmates. About 23% of deaths by suicide occur within the first 24 hr of incarceration; however, 44.8% of suicide decedents in holding facilities die within the first 6 hr of incarceration, and the vast majority of deaths by suicide (95.1%) occur during the first year of incarceration. During the time of incarceration, suicides do not differ by month or vary by season or holidays. Approximately 38% of suicide decedents are in isolation or segregation at the time of death; therefore, the majority were not housed in segregation. This is likely associated with increased monitoring by correctional staff in segregation and decreased access to methods for suicide attempts.

Risk Factors for Suicide in Community Correction

Much less research has examined suicide and self-harm in community correction settings as compared to jails or prisons. After leaving prison, offenders continue to be at risk of suicide. Offenders involved in community corrections are more likely to have a previous suicide attempt if they are young, White, and female. In addition, if the individual is abusing drugs (e.g., cocaine, opioids, sedatives, and alcohol), he or she is at greater risk of a

suicide attempt. Further, offenders on disability or retirement, with a history of abuse, or who are taking medications for mental health problems are at greater risk. When considering suicide ideation specifically, parolees are twice as likely to experience suicide ideation as nonparolees. Moreover, parolees who are married, older, and employed were not at lower risk of suicide ideation; however, among nonparolees, these characteristics are associated with decreased suicide ideation. Research also indicates that having health insurance is associated with less risk of suicide ideation. Furthermore, suicide attempts are more common among individuals who have a recent arrest when compared to the U.S. general population without a recent arrest, and individuals with multiple arrests or criminal charges are at even greater risk. Among individuals with multiple arrests, suicide attempts are more common among adults aged 25–34 years than other age groups; however, suicide attempts did not vary across gender and race/ethnicity. Notably, arrests prior to 1 year before the suicide attempt are not associated with increased risk.

Self-Harm in Corrections

Less research has specifically examined NSSI but more has focused on general self-harm (not indicating the intent to die from the self-harm). Offenders often engage in NSSI to regulate emotions and self-punish. Similarly, offenders who avoid their problem as a way to cope with them and have poorer problem-solving skills are more likely to engage in NSSI. Offenders who engage in NSSI also tend to be White, female, single, and have a lower level of education. Additionally, offenders with emotional, psychotic, and substance use disorders are at greater risk of NSSI. Furthermore, offenders with personality disorders (e.g., borderline personality disorder) are at increased risk of NSSI. Among offenders, aggression, impulsivity, and shame are associated with increased risk of NSSI; however, sadness (which is associated with NSSI among nonoffender groups) is not associated with NSSI among offenders. In addition, having a history of physical and sexual abuse during childhood and other childhood trauma is associated with NSSI among offenders. As with suicide risk, interpersonal conflict is associated with increased risk of NSSI.

A Theoretical Approach to Suicide Risk in Corrections

The corrections suicide literature is generally missing a theoretical conceptualization of suicide risk that goes beyond examining a long list of characteristics of offenders who experience suicide ideation, engage in NSSI or suicide attempts, and die by suicide. The interpersonal theory of suicide, put forward by Thomas Joiner, may provide a theoretical framework for suicide in corrections as well as other settings. This theory suggests that when individuals lack reciprocal caring relationships and are lonely (i.e., thwarted belongingness) and experience feelings of liability on others and self-hate (i.e., perceived burdensomeness), they are at increased risk of thoughts about death. When individuals experience thwarted belongingness and perceived burdensomeness concurrently, however, and are hopeless about these states changing, they are at greatest risk of suicide ideation. This theory also suggests that individuals must be capable of overcoming the pain and fear related to a suicide attempt (i.e., the capability for suicide) to be capable of a lethal or near-lethal suicide attempt.

This theory has shown promise among offenders. Research suggests that thwarted belongingness is significantly associated with suicide ideation after taking into account how depression and hopelessness are associated with suicide ideation among prisoners. In addition, prisoners experiencing higher thwarted belongingness and perceived burdensomeness report the greatest suicide ideation. Similarly, within community corrections, offenders experiencing higher thwarted belongingness and perceived burdensomeness also report the greatest suicide ideation. Thwarted belongingness is also associated with increased suicide ideation among jail inmates. Overall, these findings are consistent with the interpersonal theory of suicide. Continuing to identify theory-driven risk factors for suicide may provide a more parsimonious method of preventing suicide among individuals involved in the criminal justice system.

SUICIDE AND SELF-HARM INTERVENTION AND MANAGEMENT STRATEGIES

Suicide and self-harm (attempted suicide) are actions taken to inflict death upon oneself. U.S. governmental findings in 2016 list suicide as the 10th leading cause of death and even higher for specific groups (e.g., the second leading cause of death for those 25–34 years of age). The understanding and prevention of suicide and self-harm, as well as intervention with those who are contemplating, actively threatening, or attempting suicide are of special concern to law enforcement, correctional personnel, mental health professionals, and the community at large because of the frequency with which these professionals must

address this growing societal problem. It is important for those who intervene in these situations to understand common reasons for suicide, the characteristics of those who kill themselves, suicide assessment, skills for suicide intervention, therapeutic interventions for the prevention of future suicide attempts, and suicide by cop. A case example is provided to illustrate some of the interventions.

Common Reasons for Suicide

Common reasons for suicide are situational stressors (e.g., loss of a job, financial problems), relational motivations (e.g., ending of a relationship), existential or spiritual motivations (e.g., life having no meaning; going to be with God/a better place), somatic motivations (e.g., poor health, being in physical pain), and psychological motivations (e.g., inability to cope, feeling like a failure). A common cognitive factor for many who commit suicide is the inability to see another solution or perspective.

Assessment

The most important factor in predicting suicide is previous suicide attempts. Other factors that help assess the likelihood of suicide are (a) a detailed and imminent suicide plan (e.g., I will lay down in my bathtub and use the gun I just bought), (b) lack of resources (e.g., social support or finances), (c) being a veteran, (d) life stressors (e.g., death of a spouse, sexual assault, someone the individual knows committed suicide, impending court appearance, recent discharge from a psychiatric facility), (e) psychiatric conditions (e.g., mood disorder, bipolar disorder, substance/alcohol abuse), and (f) being symptomatic (e.g., crying, angry, abnormally withdrawn, sullen).

Assessment should be conducted relative to a person's baseline (e.g., how is the person on a good day as compared with today?). Assessment questions consider the information outlined herein and may also include questions such as What are your thoughts about hurting yourself? What is something that could happen that would push you to hurt yourself or keep you from hurting yourself? Are you on any medications and have you

been taking them as prescribed? Have you written a note or given things away? How will hurting yourself affect others? What are your religious beliefs about suicide? Is there anything else you can tell me about your thoughts about hurting yourself?

Interventions

Generally speaking, the first step in intervening with someone who is contemplating or threatening suicide is a calm (speak low and slow), trustworthy, and empathetic presence. Empathy denotes viewing a situation, cognitively and emotionally, from the perspective of another and allowing this perspective to inform one's interaction with that person. Empathy also denotes a caring demeanor that seeks the welfare of another person. The goal is to understand what the other person is going through and allow that person to vent their thoughts and emotions. A common mistake made by those who intervene in these situations is to move to problem-solving too quickly. Patience is required to allow another individual to speak about his or her emotions and perspectives until the individual believes he or she has adequately expressed himself or herself.

During this phase, the listener may hear irrational or faulty cognitions (e.g., It is all my fault, I deserve to die). To paraphrase these cognitions, and the emotions that go with them, is an effective intervention skill. To dispute these irrational cognitions, especially early on in the intervention, is another common mistake. Once the foundation of empathy, understanding, patience, and reaching the point where the other individual feels heard and validated is reached, then the person listening may offer alternative cognitions, beliefs, and perspectives. If the individual in crisis begins to adopt alternative cognitions, beliefs, and perspectives about himself or herself and his or her circumstance, the likelihood of future suicide attempts can be reduced. Long-term care of these individuals is often focused on this cognitive behavioral therapeutic approach to assisting those who have contemplated or attempted suicide. Other therapeutic interventions that can reduce future suicide attempts include brief solution-focused therapy, mindfulness training, and for suicide ideation due

to traumatic experiences, eye movement desensitization and reprocessing.

Some individuals who are actively threatening suicide may not be in touch with reality (psychosis) due to a psychiatric condition such as schizophrenia or due to being under the influence of a substance. In these cases, short and concise sentences and paraphrases can be very effective. Because of the psychosis and the individual's inability to focus attention, it may be necessary to repeat what has been said. Asking the individual to focus on the person intervening as well as his or her voice can also help the individual focus on reality instead of hallucinations. Disputing delusions (false beliefs, such as, I am the devil) is rarely effective, but placating or agreeing with said delusions is not effective either. Rather, attention is focused on reality and the situation at hand. Suggesting to the individual that he or she does not have to listen to the voices may be helpful. Even though psychotic, the individual may still be able to discern whether he or she is being lied to, bluffed, or patronized. A standard rule in these situations is to talk with someone as if you will see him or her in the same situation again in the future. Stalling for time, not backing the individual into a corner, a low tactical presence, non-threatening body language, and even allowing the individual to ingest nicotine may all be helpful in resolving the situation peacefully. Emergency detentions (whereby a police officer commits a person to an inpatient facility) and referral to a mental health professional are common practices. Although not supported by research, no-harm contracts also remain common practice.

Progress is indicated by a shift in violent statements, disclosure of personal information, moving from the emotional to the cognitive, speaking for longer periods of time, willingness to discuss topics unrelated to the crisis at hand, lower and slower speech, and developing trust and rapport with the person intervening.

A last resort, as in the case of someone who obviously is about to kill himself or herself, is the technique "clap to stop the countdown." In this instance, the person intervening claps loudly, abruptly yells, "Hey!" or shouts the individual's name in an effort to shock the individual back into coherence and away from their immediate plan.

Case Example: Suicide by Cop

Suicide by cop, or victim-precipitated suicide, is an instance in which an individual provokes, through intentional action, a law enforcement response that causes his or her death. Following is part of a transcript from a real negotiation in which *M* represents a man with knives (Mike), *O* stands for any officer talking, *H* stands for Sgt. Hester (a crisis negotiator), and *A* represents Andy (a mental health professional and crisis negotiator). As documented by Young in 2016, the transcript begins with three officers, weapons drawn, trying to talk Mike out of rushing at them with a knife from a closet.

O1—Mike, put the knife down and let's talk about this. Come on, do the right thing, Mike. Put it down.

M—Is she here?

O1—No, she's not here. They're not going to let your mom in here because you're too agitated.

M—I'm agitated because she f—ing ain't here.

O1—You're not going to get to talk to her until you put the knife down and come on out.

M—Why are you watching from the back? SWAT's already here. I'm outta here, man.

O2—We've got negotiators here.

M—Okay, well, tell them to get out of here, man. They're f—ing . . . They're drilling through the f—ing walls. (hallucinating)

O1—They're not drilling through the walls.

M—And, there's f—ing wires along . . . You . . . go ahead and shoot me, man . . . Hello? Hello?!

O2—I don't want to have to hurt you. Don't come out of the closet any further, man. You got that knife. You're dangerous. Okay?

M—Aw, man. They're right behind that thing, man.

O2—There's two other guys over here, okay. There's two other guys over here.

M—(incomprehensible arguing) . . . trying to get me . . . No wires, man! What the f— is that? You're trying to trick me, man!

O3—There's a negotiator standing right here.

M—No f . . . ! I know, they're probably trying to trick me to get me to . . . no b—s—, tell him to come out.

O3—Alright. This is Andy Young. He's a negotiator with the SWAT team. Okay?

(Andy steps out so Mike can see him).

M—Why are they . . . ?

A—I'm sorry? (low, slow, calm tone)

M—Why are they trying to get me right here with these f—ing things right here, man?

A—No, there's nothing there that's going to get you. . . . He's with me. We're both doing the same thing for you.

M—It ain't a good day.

A—No, it's not. Can you tell me about it?

M—Nah. I want to die.

A—Well, we don't want that. Okay? If you want to talk to your mom, all you got to do is put the knife down.

M—Get in those handcuffs, man, and then I'll talk to her from jail.

A—You want to talk to her later?

M—You're lying, man.

A—You're worried I'm lying to you?

M—I'm going to give up the knife, and I'm going to jail. No talking.

A—No talking to who?

M—To anyone. Right?

A—That's up to you.

M—No, I'm saying that's what's going to happen.

A—Well, you can talk to your mom before you leave this house.

M—You're lying.

A—I've got no reason to lie to you.

M—You want to see a murder?

A—Not today. But . . . I've seen plenty. . . . Nobody wants to. Okay?

M—I do.

A—Why is that? Everything's going to look different tomorrow.

M—Why's the black one trying to get right there, man?

A—He's with me.

O—This is Sergeant Hester. He's a SWAT negotiator.

(Ross, then Andy takes their helmet off in an attempt to calm Mike.)

M—Gotta be the other . . . man. . . . I ain't going to prison.

A—We're standing here because nobody wants you to get hurt.

M—That's it, man. I ain't going back to no prison.

H—Why would you go to prison?

M—Why wouldn't I not? . . . Whacha tryin' to do? Tase me with that f . . . ing thing?

H—No, sir.

A—What do you see?

M—Something? He keeps looking down.

A—Alright, tell me what you see. What do you see?

M—Well, I'm probably going to die. I'm probably going to die.

A—You know, nobody wants that, right? Nobody wants to hurt you.

M—It's over. It's gonna happen.

A—Don't let it happen. Don't let it happen.

M—(Pained groan) Look . . . it hurt like a m— er f—er.

A—What hurt?

M—I don't give a f— about it hurting. I'll be in pain for the rest of my life. Jesus, forgive me . . .

A—Are you in pain right now?

M—(Praying) Forgive me for everything . . .

A—Mike, are you hurting?

M—(Mumbles and prays.)

A—Do you have children to take care of?

M—(Mumbles and prays.)

A—Do you have children to take care of?

M—You're trying to get me to talk. It's over. (Pained groans.)

A—Are you hurting?

M—It's gonna happen. It's gonna happen.

A—Can you look at me?

M—I gotta build myself up, man. It's gonna happen.

A—Well, we don't want it to happen. Why do you want it to happen?

M—I don't want to sit in no f—ing holding cell today, man.

A—You don't want to be in a holding cell? What do you want?

M—What I want, y'all can't give, man. I can't go back. You can't just let me free . . .

A—Well, we want you to go to the hospital.

M—You're going to take me to jail, man.

A—No, we want you to go to the hospital.

M—You just tried to give him the signal to shoot me with that thing, man.

A—Nobody wants to shoot you. We got an ambulance outside; we want to take you to the hospital.

M—I'm not getting shot by no f—ing taser, man.

A—That's fine. You've just got to put down the knife. We want to take you to an ambulance.

M—I'm going out in an ambulance? (sarcastic)

A—Yeah, we want to take you to an ambulance, but we don't want you hurt.

M—I'll be dead, I won't be hurt. . . . Something's going on man. There's too much air coming in that wasn't coming in before, man.

A—You feel air?

M—Yeah.

A—Where do you feel air coming from? This way?

M—Behind you, man.

A—From behind me?

M—You're trying to play with my f—ing head, man.

A—Sir, I just want you to come out without the knife. (pp. 162–170)

This case study illustrates many of the intervention skills outlined and underscores the seriousness of suicide intervention. Proper care, patience, understanding, training, and intervention skills can certainly reduce the likelihood of the completion of suicide.

SUICIDE AND SELF-HARM OFFENDER-SPECIFIC SCREENING TOOLS

While the terms *suicide* and *self-harm* are often used interchangeably, it is important to be clear that they are conceptually different. Suicide is a self-inflicted act with the intention to cause death, whereas an act of self-harm may be the precedent

to an act of suicide, but it can also exist as a concept in its own right as an intentional act of harm without suicidal intent. Self-harm is intentional, often repetitive, and often constitutes a coping mechanism to provide temporary relief from emotional distress. The crucial differentiation between suicidal behavior and self-harm lies in the nature of motivational intent underlying the action. This distinction makes the early identification of those who are at risk of self-harm or suicide more difficult and the screening of potential at-risk populations more complex. It has been argued that as the impact, treatment pathway, and even costs are similar for both groups, this difference is considered irrelevant for the screening of these behaviors. Skegg in 2005 suggested that self-harm and suicide should be considered as a continuum in the sense that self-harm covers a spectrum of behavior: The most serious form closely relates to suicide, while behaviors at the milder end of the spectrum range merge with other reactions to emotional pain. And it is this approach most commonly employed in the development of screening tools to identify those at risk of suicide and self-harm, whereby self-harm is defined as an act of self-poisoning or self-injury, irrespective of the purpose of the act. This entry addresses the prevalence of suicide and self-harm in offender populations, lists risk factors for offender suicide and self-harm, and provides an overview of assessment tools.

Prevalence of Suicide and Self-Harm

Suicide and self-harm represent a significant global health challenge. In 2014, the overall rate of suicide in the United States was 12.93 per 100,000, a 20% increase since 2005, and the rate was almost double in males aged between 20 and 35 years. The rates of self-harm were estimated to be 12 times that of suicide, with women more likely to self-harm than men.

Offender populations are some of the most marginalized people in society, with higher rates of socioeconomic disadvantage and worse physical and mental health, so it comes as little surprise that the rates of self-harm and suicide are far greater in this population than the general public. Suicide is the most common cause of death in U.S. jails, with a rate far higher than the general population at 46 per 100,000, and this has increased

12% since 2009. Epidemiological studies suggest the rate of self-harm in offender populations is 30 times that of the general population with 30% of prison populations reporting self-harm behaviors; the rate rises to 50% for female offenders.

Risk Factors for Suicide and Self-Harm in Offenders

In order to develop screening tools for suicide and self-harming behavior, a number of authors have explored the risk factors associated with these behaviors in the offender population.

Demographic and Environmental

There is clear evidence that gender plays a role in whether an individual is likely to attempt suicide or engage in self-harm, with far more women likely to engage in self-harm and more men attempting suicide. Age is also a factor: Older offenders are more likely to attempt suicide and younger offenders engage in self-harm. Being Caucasian, greater socioeconomic disadvantage, having lower educational attainment, and not being in a relationship are also strong predictors of both self-harm and suicide in offender populations. First time incarceration, long sentence, and being on remand in prison are both associated with greater risk of self-harm and suicide irrespective of age and gender. In the United States, being incarcerated in the county jail system as opposed to the state prison system is associated with a higher risk of both self-harm and suicide.

Lifetime

Previous self-harm and suicide attempts are strong predictors of future self-harm and suicidal behavior. Childhood abuse, either physical or sexual, has been associated with greater risk, and childhood sexual abuse is particularly associated with higher risk in offender populations. Poor social networks, isolation, and the loss of significant others are also associated with increased risk.

Mental Health

Clinical diagnosis of depression, psychoses, or a history of substance abuse has been found to

increase the risk of future self-harm and suicide in both male and female offenders. For women, in particular, a clinical diagnosis of personality disorder is associated with an increased risk of self-harm.

Coping Style

Studies in offender populations have identified weaker cognitive coping strategies, particularly the use of avoidant strategies, and poor problem-solving skills to be associated with increased risk of self-harm and suicide. Greater interpersonal conflict, internalization of conflict impulsive reaction, and resentment are all associated with greater risk of both self-harm and suicide.

Emotions

Increased risk has been found to be associated with higher self-rated aggression, greater impulsivity, and more severe feelings of shame. No increase risk has been associated with general dysphoria or sadness.

Screening Tools

The risk of suicide and self-harm presents a major challenge to managing the health of offender populations, and there is a clear need for efficient screening tools to identify those at risk. In addition to being diagnostically efficient, screening tools need to be simple to implement, complete, and interpret.

Interpreting the Tools

A screening test aims to identify those at increased risk in a timely manner in order to facilitate access to appropriate intervention and improve outcome. A screening tool will provide an indication whether an individual is positive or negative for increased risk. No screening tool is infallible, so those identified as being positive will include a proportion who are not truly positive and those identified as being negative will include a proportion who are not truly negative. The sensitivity of a screening tool is the proportion of those who screen positive who are truly positive (i.e., the proportion of those identified as being at

increased risk who go on to engage in self-harm or attempt suicide) and the specificity is the proportion of those who screen negative who are truly negative (i.e., the proportion of those identified as being at no increased risk who do not later engage in self-harm or attempt suicide). The true positive and true negative rate is established by reference to a gold standard, sometimes a different test that is known to accurately identify positive and negative cases, or a behavioral outcome measured at some point in the future. While a hypothetical gold standard would be 100% sensitive and 100% specific, it will often be far more complex to administer than a simple screening test.

The efficiency of a screening tool involves a trade-off between sensitivity and specificity in order to avoid misclassification and aims to identify as many truly positive individuals and as many truly negative individuals as possible. As the potential implications of misclassifying an individual as negative for suicidal intent are high, sensitivity of the tool may be prioritized over the specificity, maximizing the identification of positive cases at the risk of misclassifying negative cases as positive. In addition, the predictive value of a screening tool is a useful concept to take into account. The positive predictive value is the proportion of those who are classified as positive who go on to commit suicide or engage in self-harming behavior, and the negative predictive value is the proportion of those who are classified as negative who do not go on to commit suicide or engage in self-harming behavior.

When assessing the efficiency of a screening tool, the tool must be compared with a gold standard, a criterion test that is established as a diagnostic test or benchmark. As noted earlier, a hypothetical gold standard test is considered to be 100% sensitive and 100% specific. In mental health research, gold standard tests are rare and where they do exist they are usually based on historical report of populations who are known to be at risk, and as such, the interpretation of any screening tools should always carefully consider the context of the gold standard comparison.

Review of Screening Tools

While a number of studies have been conducted to explore the utility of screening tools to identify

those at increased risk of self-harm and suicide, there is a paucity of research focusing on offender populations. A major issue arises when researchers and clinicians simply adopt screening tools used in general or psychiatric populations to offender populations without careful consideration of the differential nature of the environment. Offenders often have higher rates of depressive symptoms; they have often experienced significant psychological trauma, have been removed from their usual environment, and have limited access to their social networks. Screening instruments that assess feelings of guilt, perceptions of punishment, and lack of control have limited validity in the offender population.

A comprehensive systematic review of screening tools focusing on suicide and self-harm in offender populations was conducted by Amanda Perry and colleagues in 2010. The review identified 404 research studies in the published literature and an additional 75 studies that had not been published. Only five studies assessing the screening properties of four instruments were considered to be of sufficient scientific quality to be considered in detail. Of these four instruments, two were found to have poor diagnostic properties and unacceptable predictive value: the Suicide Checklist and Suicide Probability Scale. Two instruments demonstrated acceptable levels of diagnostic properties and acceptable predictive value: Suicide Concerns for Offenders in Prison Environments and Suicide Potential Scale. In addition, a review by Simon Gilbody and colleagues 2014 identified the Beck Hopelessness Scale as being useful for screening offenders for risk of self-harm.

Suicide Concerns for Offenders in Prison Environments

This 28-item self-report instrument was developed specifically to identify offenders at increased risk of suicide and self-harm. The instrument assesses risk across two domains. The first relates to factors associated with a protective social network and assesses the presence of support, innate coping skills, and problem-solving abilities. The second relates to factors relating to depression, hopelessness, self-harming history, and suicidal ideation. Each question is rated on the Likert-type

scale, scored 0–5, ranging from *strongly disagree* to *strongly agree*, with a score of 38 or more on the first factor and 30 or more on the second factor being indicative of a positive case. The instrument is quick and easy to complete and has demonstrated good psychometric properties in differentiating between offenders with a history of self-harm and those without. As a screening tool, it demonstrates acceptable levels of sensitivity at 81% and specificity at 71%. Suicide Concerns for Offenders in Prison Environments demonstrated excellent positive predictive value (94%) and acceptable negative predictive value (55%).

Suicide Potential Scale

The 9-item Suicide Potential Scale is a clinician-completed scale assessing previous suicide attempts, recent psychological or psychiatric interventions, recent loss of a significant other, previous use of alcohol and illicit substances, symptoms of depression, current major problems, current suicidal ideation, and the existence of a suicide plan. Each item is scored as *being absent*, score 0; or *present*, score 1. A total score of 3 or more has been reported of having high sensitivity, 86%, and high specificity, 80% (although there is no detailed evaluation of the positive and negative predictive value of this instrument).

Beck Hopelessness Scale

The 20-item self-completed instrument explores the individual's negative perception of the future across three domains: feelings about the future, loss of motivation, and expectancy. Scoring requires access to the scoring template, and a score of 8 or more is considered indicative of moderate risk of self-harm and suicide. Meta-analytic reviews of the instrument suggest high levels of sensitivity for both suicide and self-harm, 80% and 78%, respectively, but modest levels of specificity for suicide and self-harm, both 42%.

Final Thoughts

While a great deal of work has been undertaken to understand how to identify those at high risk of suicide and self-harm in the general population, there has been little work undertaken with offender

populations. Where work has been conducted, it needs to be interpreted with caution. From a methodological perspective, the majority of research has focused on identifying constructs in populations who are known to be at risk and then comparing these to those who are not considered at risk, but one needs to be wary that past behaviors may not be predictive of future behavior. In addition, since self-harm and suicide are more prevalent in offender populations, needs assessment and care planning are critical aspects of health-care provision, and more research is needed on efficient tools to identify those at risk of suicide and self-harm as part of a comprehensive assessment package.

SUICIDE AND SELF-HARM SCREENING TOOLS

Suicide refers to the act of intentionally taking one's own life while self-harm is the act of intentionally injuring oneself. Although self-harm such as intentionally cutting oneself can be associated with suicidal ideation, it is also known to be an impulsive behavior used by many as a way of attempting to cope with emotional pain. The National Center for Injury Prevention and

Control reported that in 2016, suicide was the 10th leading cause of death in the United States for all ages. In 2016, there were nearly 45,000 suicides in the United States, and 9.8 million adults reported having suicidal thoughts at some point during that same year. Suicide has been estimated to cost more than US\$50 billion in combined medical and work loss. Self-harm such as cutting and burning oneself are on the rise, and hospitals have reported an increase in the number of adolescents and young adults hospitalized for self-harm. Given these facts, it is not surprising that researchers have spent much time and energy over the years developing tools that help to screen for risk factors related to suicide and self-harm.

Risk Factors for Self-Harm and Suicide

Research has pointed to a number of factors that are correlated with self-harm and suicide. Based on epidemiological data, most cases of self-harm involve cutting behavior by adolescent females. People who commit suicide are more likely to have a mental illness, a family member who has committed suicide, or a history of drug and/or alcohol abuse. Although people without mental illness have been known to commit suicide, the majority of people who commit suicide have a mental illness, primarily a depressive disorder. Consistent with a cognitive behavioral model of mental illness that proposes that a person's feelings and behaviors are a response to errors in thinking and a faulty belief system, people who engage in suicidal behavior have been found to have some common beliefs that fall into one of three categories: that suicide is the only solution to their problems, that loved ones are better off without them, that they deserve to die, or a combination of all three. For self-harm behaviors such as cutting or burning oneself, risk factors may include peer or parental conflict, depression, personality disorders, or a combination of multiple factors. Understanding these correlates of suicidal behavior and self-harm has helped to guide the development and format of screening tools designed to assess risk of these behaviors.

Introduction of Screening Tools

One of the first paper-and-pencil screening tools that offered a numerical value to assess depression

was the Beck Depression Inventory, developed in 1961 by Aaron Beck. This 21-item multiple choice assessment relies on endorsements that measure the presence and severity of certain thoughts and feelings that have been found to correlate with depression. While researching the Beck Depression Inventory, Beck found that people who reported stronger feelings of hopelessness were more likely to be suicidal. This discovery led Beck to publish the Beck Hopelessness Scale, a screening test that more specifically assessed feelings of hopelessness, which Beck believed to be a strong predictor of suicidal ideation.

As research into suicide and self-harm has progressed, numerous screening tools have emerged to assist health practitioners. Moreover, self-harm is no longer viewed as a precursor to suicide. It certainly can be; however, self-harm behavior is beginning to be understood as a clinical phenomenon quite separate from suicide. In addition, research finds that risk of suicide and self-harm varies depending on a number of demographic variables (e.g., age, sex, ethnicity) as well as situational variables (e.g., mental illness, stressors, drug abuse). As a result, screening tools have been developed to assess suicide and self-harm risk across a variety of demographics and situations.

Current Screening Tools

Most often, the best way to assess for self-harm or suicide is to simply ask the individual directly. However, in many cases, it is not possible to do so. For example, some people are embarrassed or ashamed to respond to direct questions. Also, there are situations such as when dealing with groups of people (e.g., patients at medical facilities, inmates at prisons, students in academic settings) when individual verbal assessments are not feasible. Consequently, it is useful to have screening tools that can help mental health professionals identify individuals at risk of self-harm and suicide. Although a simple Internet search might yield numerous hits that describe screening instruments designed to identify individuals at risk of self-harm and suicide, readers are cautioned that a screening instrument that claims to accurately predict risk of dangerous behaviors must be valid and reliable. In other words, the authors of a good screening instrument should provide empirical

evidence that the screening tool accurately measures what it claims to measure.

In order to ensure that screening tools accurately assess risk of suicide and self-harm, they must be studied with regard to their validity and reliability. Validity refers to the extent to which the screening tool measures what it is intended to measure. For example, if a tool claims to measure one's risk of self-harm, there must be clear definitions of what *self-harm* actually means. Does pinching oneself until it hurts constitute self-harm or is some type of physical injury as a result of the pinching necessary? Most authors report two types of validity to support the value of their assessment tool. The first is called *construct validity*, and typically, a screening instrument will be accompanied by evidence (usually in the form of a statistical correlation value) that across several studies using different participants, all participants understood the term or *construct* (i.e., self-harm) in a similar way. The second type of validity commonly reported is *concurrent validity*. Concurrent validity refers to how strongly the tool correlates with other tools that measure similar constructs and have been previously endorsed as having strong validity.

Having strong reliability is another important measure of a good screening tool. Most authors report a form of reliability called *internal consistency reliability*. To establish this, the individual items that make up the screening instrument are rearranged to mix up the order in which they are presented. For example, if the screening tool has 20 items and the original form is numbered 1–20, the same items might be split in half and presented in various orders to be sure that the individual items, regardless of the order, are contributing to the same outcome. There is a mathematical way of doing this and coming up with an average result for all the possible orders called *Cronbach's α* —a single index reflecting the tools reliability.

Although there are hundreds of screening instruments, both formal and informal, available on the Internet, the following list of suicide and self-harm screening instruments represents a sample of those that have been subjected to scientific research and have demonstrated good validity and reliability for their respective areas of focus.

SUICIDE DURING INCARCERATION

Death by suicide among prison inmates is a major problem that plagues the correctional system. Although suicide rates have declined since the 1980s, it is one of the most prevalent causes of death for prisoners. Long-standing and widespread acknowledgment of this problem has led to investigations that have provided in-depth data about suicide among prison inmates, including which prison inmates are most at risk of suicide, when and where suicides occur within prisons, and how prison inmates engage in suicidal behavior. Despite these efforts, relatively little is known about why prisoners die by suicide and how correctional mental health providers can predict and prevent death by suicide among prisoners. This entry provides a general overview of the problem of suicide among prisoners in the United States and Canada, some prevention and response methods used in prisons to address this problem, and a brief consideration of why prisoners may be confronted with the desire to die by suicide.

The Problem of Suicide Among Prisoners

Although suicide rates among prisoners declined dramatically from the 1980s to the 1990s, rates remained relatively stable from 2001 to 2013, representing over 4% of prison inmate deaths in

state prisons and over 6% of prison inmate deaths in federal prisons in the United States. Suicide is the second leading cause of death among prison inmates (behind physical illnesses, which total over 90% of all prison inmate deaths). With almost no exception, this fact holds true regardless of gender, race, and age-group. One notable exception is that for state prisoners under 18 years of age, suicide surpasses physical illnesses as the most common cause of death, with a mortality rate about twice that of most other age groups. Although suicide rates are almost always the second leading cause of death for prisoners, some groups of prisoners may be at greater risk of suicide than others. For example, White prisoners have the highest mortality rate due to suicide, followed by prisoners of *other* race, Hispanic prisoners, and finally Black prisoners. For prisoners 18 years of age and older, mortality rates increase slightly as age increases.

Suicides among prisoners do not cluster at any point during prisoners' time incarcerated. Specifically, less than 10% of suicides take place during the first month of prison incarceration, about 65% occur sometime after the first year, 33% occur sometime after 5 years of incarceration, and about 15% occur after a decade of incarceration. Time of day is equally well dispersed, with nearly proportionate numbers occurring in the morning, afternoon, evening, and overnight. Although timing appears unrelated to suicide in prisons, about 87% of inmates who die by suicide do so in their cell, and not surprisingly, these inmates often have a single cell (i.e., no cell mate). Suicide often occurs in administrative segregation or other secure housing unit locations, although it is unclear whether these types of housing environments actually promote suicidal behavior or if prisoners experiencing more suicidal ideation are more likely to be placed in these locations.

Approximately 80% of prisoners who die by suicide do so by hanging, which may be because it is a simple, easily accessed, and well-known method for suicide. This method of suicide does not actually necessitate hanging, as it can be completed in various positions (i.e., lying down, kneeling, sitting, standing), and in fact requires little pressure applied to one's throat. Death by drug overdose, particularly psychotropic medication, is the second most common cause of suicide among prisoners.

Prevention of Suicide Among Prisoners: Assessment

Prison systems continue to increase attention toward refining suicide assessment methods; however, the *drive-by* technique remains the most basic and frequently used method to detect suicide ideation among prisoners. This method entails simply asking a prisoner if they are suicidal. It is commonly employed because it can be completed in a few seconds, and therefore, a large number of prisoners can be assessed without consuming correctional mental health providers' time. In addition, it requires no funding for formal screening materials. Given the often-insufficient number of mental health providers in prisons, this *drive-by* technique is often adequate and appropriate when used with prisoners who are at low risk of suicide.

Unfortunately, prisoners may underreport or deny suicide ideation because of a desire to avoid perceived unwanted consequences (e.g., being seen as weak by fellow inmates, having the cell searched for dangerous materials, being sent to a suicide watch cell, reducing the likelihood of parole). On the other hand, some inmates may falsely report suicide ideation for manipulative purposes, such as reassigned housing away from other inmates who are harassing them, or simply to be disruptive to correctional staff. Research has demonstrated, however, there is no reliable way to distinguish between prisoners who report suicide ideation and will make a suicide attempt versus those who are *faking it*, and so it is emphatically stated in prisons' policies that all correctional staff must take all reported suicide ideation seriously.

Although there is no specific type of prison inmate who is particularly at risk of suicide, certain characteristics and experiences are related to increased incidence of attempted and/or completed suicide. These include

- a history of past suicide attempts,
- past and/or present severe mental illness (e.g., major depression, psychotic disorders),
- current severe medical problems,
- recent legal status changes (e.g., denied appeal, additional sentence imposed for crimes committed during incarceration),
- recent sexual and physical victimization, and

- problems in relationships with people outside of prison as well as staff and other inmates within prison.

Prisoners who are at higher risk of suicide require more extensive assessment than the *drive-by* technique. Although no standardized assessment method has been established across prison systems, an example of a thorough assessment is the Chronological Assessment of Suicide Events (CASE) approach. This approach entails an in-depth interview intended to procure honest, accurate information about a range of sensitive topics that respondents may be hesitant to discuss. As applied to suicide, the CASE approach is initiated with an in-depth discussion with the prisoner of the recent event or situation that prompted concern about suicide, followed by an exploration of any recent suicidal behavior, then more distal suicidal behavior, and finally shifting toward present ideation and plans for suicide or self-harm.

The effectiveness of the CASE approach lies in the process of how these topics are discussed. The interviewer strives to reduce shame the prisoner may be experiencing by utilizing empathic questioning (i.e., acknowledging the individual's pain and the difficulties he or she is facing). At the same time, questions focus on concrete behaviors and thoughts, for example, urging the prisoner to create a detailed timeline of thoughts and behaviors for a prior suicide attempt. To elicit sensitive information and reduce the chance of underreporting or denial of actual experienced suicide ideation, the interviewer may frame questions in ways that assume a behavior or experience has actually occurred (e.g., "What other ways have you harmed yourself in the past?"). Similarly, when questioning the frequency of past behaviors or experiences, the interviewer may overestimate the incidence to avoid minimization in a prisoner's response (e.g., "How many times have you tried to overdose before—50?"). In instances when a prisoner being interviewed denies a more general past experience (e.g., denies ever having harmed him or herself before), an interviewer using the CASE approach may ask more specific, targeted questions (e.g., "What about burning yourself; have you ever done that before?") to obtain more accurate information

by normalizing these experiences and assisting the prisoner in recalling specific past experiences he or she may have otherwise forgotten.

Prevention of Suicide Among Prisoners: Response

If, as the result of an assessment, a prisoner is determined to be at risk of suicide, action is then taken to help ensure his or her safety and promote psychological recovery and desire to live. In the past, use of suicide contracts was a popular means of attempting to reduce suicidal behavior. A *suicide contract* consists of a written agreement that the prisoner will not engage in suicidal behavior. Research has consistently demonstrated, however, that a suicide contract by itself is not effective in the reduction or prevention of completed suicides or suicide attempts. Furthermore, legal case review has demonstrated that suicide contracts are not an adequate defense against legal culpability for prison systems. However, some mental health providers defend the use of suicide contracts and suggest the following benefits of these contracts:

- they express concern for, and initiate empathic communication with, the prisoner about his or her current situation and experiences;
- they promote a sense of self-control in the prisoner; and
- they can be elaborated to identify resources, support systems, and coping mechanisms the prisoner should utilize when experiencing suicide ideation.

Given that correctional mental health providers often experience a false sense of safety for both the prisoner and the prison system when using a suicide contract, many institutions and systems have instead adopted the use of suicide safety plans. A *suicide safety plan* incorporates many of suicide contracts' beneficial aspects but does not constitute an unrealistic, absolute agreement about a prisoner's behavior.

In addition to creating a safety plan for a prisoner who may be at risk of suicide, correctional mental health staff may improve suicide prevention efforts by increasing the monitoring of these prisoners. This may include frequent, informal check-ins by mental health and other correctional

staff, scheduling more frequent sessions with correctional mental health providers, conducting regular follow-up suicide assessments, and promoting the prisoner's attendance and participation in group therapy offered within his or her institution. When a prisoner presents at higher risk of suicide, staff should evaluate the safety of the prisoner's cell by looking for accumulated medicine, sharp objects, and physical features of the cell from which the prisoner might hang him- or herself (e.g., protrusions and holes or screens to which something may be tied to or around).

When a suicide attempt appears imminent for a prisoner, he or she is often placed on suicide watch. *Suicide watch* typically includes placement in a specified cell that is designed with the prisoner's safety in mind, with physical features that inhibit self-harm, provision of safer bedding and clothing (e.g., a suicide smock), and consistent observation of the prisoner. Observation is sometimes conducted with video monitoring, but safety is best ensured when observation is conducted directly. Although specific policies vary across prison systems, the general standard is that restrictions on the prisoner are as minimal as possible to ensure his or her safety. Efforts are made to maintain the prisoner's routine when possible, including provision of food, self-care and hygiene, and recreational activities and materials. Furthermore, the goal is to help the prisoner's psychological state improve so that he or she can be moved out of suicide watch as soon as possible.

Understanding the Why of Suicide Among Prisoners: Theoretical Considerations

Research has illuminated a list of risk factors associated with suicidal behavior among prisoners, but this has done little to improve understanding of why some prisoners have a desire to die by suicide. Some theoretical considerations may be helpful in this regard. One such consideration is that suicidal prisoners may be experiencing *psychache*, a term that Edwin Shneidman developed to convey an experience of severe psychological pain. Although severe depression and hopelessness may promote suicide ideation, a minority of individuals with these experiences

die by suicide. Instead, it is anguishing psychache that is postulated to be the intolerable experience that promotes suicidal behavior. Another consideration is delineated by Thomas Joiner's interpersonal theory of suicide, which states that a person will experience a desire to die by suicide when he or she feels isolated and unsupported by others (i.e., thwarted belongingness) and inconvenient, bothersome, or troublesome to others (i.e., perceived burdensomeness) for which the individual experiences self-loathing. This theory states, however, that humans have evolved negative reactions toward self-harm that are extremely difficult to overcome, and so in order for a person to die by suicide the desire to die must be accompanied by the acquired capability to perform the suicidal behavior, which may develop in part through prior suicide attempts, exposure to violence, and traumatic experiences. This theory appears particularly applicable to prisoners, whose circumstances promote a sense of thwarted belongingness and perceived burdensomeness, and who tend to have more experiences that create the acquired capability to engage in behavior that results in suicide.

SUICIDE RISK AND SELF-HARM

Suicide is a global public health problem: In 2012, there were an estimated 800,000 deaths worldwide, and by 2020, this figure is expected to rise to 1.53 million. This represents an annual, global, age-standardized suicide rate of 11.4 per 100,000 population. The figures suggest that death by suicide causes a significant public health problem which is likely to be underrepresented due to differences in reporting systems, the sensitive nature of the topic, and the legality of suicide in some countries. Whatever the shortcomings of current underreporting, it is a fact that rates of self-harm and suicide are far higher among offender populations than the general population. That means that assessing who is at risk and determining how best to intervene are important topics. This entry addresses self-harm and suicide in prisons, offender suicide and self-harm risks factors, and management of suicide and self-harm in prisons, including psychological interventions and problem-solving skills.

Self-Harm and Suicide in Prisons

Rates of self-harm and eventual suicide in prisons far exceed the rate within the general population. Estimates of self-harm differ within different offender populations and by country. Part of the reason for these differences surrounds how *self-harm* is defined. That being said, research has estimated that between 30% and 49.4% of prisoners worldwide engage in some self-harming behavior, with the rate reportedly higher in females. A case-control prison study estimated that the annual incidence of self-harm of people in custody was between 5% and 6% for men and teenage boys and between 20% and 24% for women and adolescent girls. The measurement of, and thus the exacerbated risk of, self-harm behavior in prison is particularly difficult because individuals often repeatedly harm themselves and

such repetition has been shown to increase the risk of ultimate suicide. Eventual suicides are 5 times higher in male prisoners and 20 times higher in females than in general population controls. As many as 1.8% of people who harm themselves die by suicide in the year following the incident, and in the offender community, as many as 8.5% die by suicide over a 22-year period.

Risk Factors

Two systematic reviews have examined the risk factors associated with self-harm in prisons. Evidence from these reviews and other studies suggests that White ethnic origin, a history of self-harm, mental disorders, substance misuse, violent offending, and suicidal ideas are risk factors for self-harm and attempted suicides. Additionally, the risk of death is highest in the immediate period after prison reception. In male prisoners, deaths occur most typically in local adult prisons in the United Kingdom or in jails in the United States. These prisoners are particularly vulnerable while on remand and awaiting a sentencing decision. What is difficult to ascertain is that such risk factors are already exacerbated in the prisoner population, making it challenging to identify those most at risk and to determine how to intervene.

Management and Interventions

Management of self-harm and attempted suicide in prisons often represents a logistically complex challenge, not least because of where the individual is accommodated and its associated environment. Most prisons (80%) in the United States and all in the United Kingdom adhere to a Suicide Prevention Policy. However, a review of U.S. prisons suggested that only 15% of prisons meet clinical recommendations for the scope of these policies. In the United Kingdom, a scheme referred to as *Assessment of Care and Custody Teamwork* is used as a mechanism for developing a care plan and monitoring someone who is deemed to be at risk. This management tool facilitates communication between staff and prisoner, linking risk factors to level of risk in order to ascertain the best possible approach. The Assessment of Care and Custody Teamwork system provides multidisciplinary support to prisoners at risk of harming

themselves. The plan encourages staff to work together to provide individual care to prisoners in distress, to help defuse a potentially suicidal crisis, or to help individuals with long-term needs (e.g., those with a pattern of repetitive self-injury). Prisoners are fully involved in the Assessment of Care and Custody Teamwork process and their individual care plan with the aim of reducing distress.

Psychological Interventions to Reduce and Prevent Suicide

Evidence surrounding how best to treat people who self-harm in prison is limited. Treatment in the United Kingdom has focused on monitoring and safety (as opposed to treatment *per se*) to ensure that staff are vigilant in their approach. Two systematic reviews have evaluated the impact of psychological interventions in reducing self-harm behavior in the general population within the *community*; however, possible treatment options for offender populations in the United Kingdom have only been tested in two pilot randomized controlled trials (RCTs) of cognitive behavioral therapy and interpersonal psychotherapy and a feasibility study of problem-solving skills.

Cognitive Behavioral Interventions

Evidence for the effectiveness of cognitive behavioral therapies comes from a host of studies in the general population, including those focusing on suicidal behaviors. The evidence suggests such interventions are most effective when specifically targeted and designed to focus on suicidality. In addition, in 2011, cognitive behavioral therapy was recommended by the National Institute for Health and Clinical Excellence as one of the recognized treatments for reducing suicidal ideation.

Although this evidence is limited to community populations, one study evaluated the impact of cognitive behavioral treatment for offenders in prison. This study used a pilot RCT to compare a cognitive behavioral therapy in addition to treatment as usual in a group of 62 participants. The trial specified the primary outcome of self-harm behavior within 6 months. A number of secondary outcomes were also measured including suicidal

ideation, psychiatric symptomology, personality dysfunction, and psychological determinants of suicide including depression and hopelessness. The authors found that participants receiving the therapy (in addition to usual care) showed a significantly greater reduction in suicidal behavior in comparison to participants receiving usual care only. A number of other significant improvements were reported, including a reduction in psychiatric symptomology and personality dysfunction. The study showed that the delivery of a cognitive behavioral therapy was feasible within the prison environment and showed significant promise for evaluating the therapy in a larger RCT.

Interpersonal Psychotherapy Interventions

The second trial employed the use of interpersonal psychotherapy with women in prison. The findings of the study showed general improvements in both groups across depression, hopelessness, and suicidal intent. This suggested that for women to improve they might not necessarily require intensive interpersonal psychotherapy treatment. In this trial, the intervention employed varied between four and eight sessions of therapy lasting 50 min per session.

Problem-Solving Interventions

Two systematic reviews provide tentative support for the use of problem-solving techniques in the repetition of self-harm behavior, and an updated review shows inconsistent findings for evidence to support improvement in subsequent problem-solving skills. The first of these reviews combined 2 of 6 RCTs for the treatment of deliberate self-harm behavior (containing a total of 71 and 55 individuals assigned to the intervention and control groups, respectively). The results overall showed that patients who were offered the therapy had significantly greater improvement in scores for depression and hopelessness and also, importantly, reported a greater level of improvement in their problems in comparison to those in the control group. However, because the trials were relatively small, concerns were raised about the lack of statistical power, poor description of standard care, and the inconsistent age ranges across the studies.

The second review formed part of a larger Cochrane systematic review focusing on psychological therapies for self-harm and included trials comparing problem-solving interventions alongside standard treatment. The problem-solving meta-analysis showed a trend toward reduced repetition of self-harm with problem-solving therapy compared with standard aftercare. Since these original reviews, a subsequent meta-analysis including the addition of two new trials shows modest effects in favor of problem-solving therapy for the treatment of repetition of self-harm in the community.

The last review presented an update of the original Cochrane review. This review identified greater inconsistencies which stem from a number of fundamental differences between the presentation of the results and the other reviews. Only four of the known seven problem-solving studies used to assess intervention impact on improved individual problem-solving skills (and not repetition of self-harm) were presented in one model. The authors found the model of analyses were changed by one study which applied a Zelen design, altering the significance of the studies overall impact.

Nevertheless, problem-solving therapy is an obvious choice because so many people who harm themselves report the main immediate cause as being problems in their lives. It is also known that poor problem-solving skills are associated with impulsive responses. Such actions often result in not thinking through all possible solutions to a problem and relying upon the actions of others, or waiting for a problem to resolve itself before taking an action.

The theory behind social problem-solving stems from a concept originally outlined by psychologists Burrhus Skinner and James Davis in the 1950s and 1960s. These influential psychologists were among the first to identify problem-solving as a self-directed cognitive behavioral process. The process involves an individual attempting to identify or discover effective or adaptive ways of coping with problematic situations. They argued that the role of coping within problem-solving was recognized through the use of two different information processing systems. These are referred to as the *automatic* or *experiential system* and the *nonautomatic* or *rational system* which includes rational problem-solving. Automatic responses often result in rapid decision-making and are instinctively

validated as *the right decision*. In contrast, the rational system is a somewhat slower process whereby the person takes his or her time to deliberate and as a consequence makes a logical decision based on all the available evidence.

The link between suicide and self-harm behavior and problem-solving skills has been demonstrated by a number of researchers. In particular, research by Thomas D’Zurilla noted that individuals who are *suicide prone* have negative thoughts and feelings about problems. Such individuals often perceive problems as some sort of a threat to their well-being. As a result, they tend to blame themselves for problems when they occur and doubt their own ability to solve problems effectively. These suicide prone individuals are more likely to view problems as unsolvable and to feel distressed and upset when faced with a problem.

Other characteristics of *suicide prone* individuals include a host of other negative behaviors. These are often associated with an avoidance of problems. For example, instead of facing problems as they arise, and being persistent in their problem-solving efforts, suicide prone individuals are likely to either avoid problems or respond impulsively. This leads to individuals putting off their problems for as long as possible, waiting for problems to resolve themselves, or trying to shift the responsibility for solving problems on to others. When responding impulsively, the person does attempt to solve problems, but these attempts are not well thought out. Avoidant and impulsive responses are not likely to result in effective problem-solving and thus risk reinforcing the negative beliefs and feelings.

A New Model

A study funded by the National Institute of Health Research in the United Kingdom evaluated the feasibility of implementing a problem-solving training model for prison staff and prisoners at risk of repeat self-harm. This study was conducted in four prisons in the North of England and considered whether it is possible to train prison staff (i.e., chaplaincy, management, prison officers, education, and health-care staff) and for those staff to cascade the skills to prisoners at risk of suicide and self-harm behavior. The study is using

an adaptation of a community problem-solving model which was originally devised in New Zealand for patients at risk of self-harm in the community. The adaptation process was thought to be important to ensure that both staff and patients felt that the training and intervention delivery was applicable and relevant to the prison setting. The study resulted in training 280 staff, and 48 prisoners at risk received the intervention. The training used a series of case studies and featured the seven-step problem-solving model:

Step 1: Getting the right attitude—The first step involves identifying whether the client has a negative attitude toward problem-solving (i.e., avoiding problems, being frustrated by problems and taking impulsive actions) versus someone who has a positive attitude (i.e., facing the problem, taking steps to solve it, and using a rationale problem-solving approach).

Step 2: Reflecting and recognizing triggers—The training introduces the idea of recognizing problems and trigger factors; the process of problem-solving involves getting the client to identify thoughts, behaviors, feelings, and physical symptoms associated with his or her particular problem.

Step 3: Defining a problem clearly—Selecting and defining a problem is helpful in turning ill-defined problems such as “My life is a mess” into a well-defined problem which the client has control over. Picking suitable problems will use criteria including ease of solution (quick wins boost confidence), urgency, or salience to the prisoner.

Step 4: Brainstorming solutions—Facilitators are asked to work with a client to discuss what possible options are available to resolve or improve the situation. Brainstorming is a method of generating as many possibilities and alternative solutions to the problem without evaluating the potential usefulness. It is useful to split solutions into the *practical* (i.e., steps to reduce or resolve problems) and the *emotional* (i.e., steps to deal with the consequences of problems that can’t be immediately resolved).

Step 5: Decision-making—Once the client has identified a number of potential solutions, the next step is decision-making. In this stage, a more in-depth examination of the solutions allows the individual to weigh the advantages and disadvantages of potential solutions. The next step is for the individual to identify which of the potential solutions

he or she would like to work and develop a plan for how to tackle the problem.

Step 6: Making a plan—The final stages of problem-solving involve the client implementing or carrying out an action plan. This should be a step-by-step process that is used to transform the chosen solutions into concrete actions. A specific, measurable, achievable, relevant, time-bound plan which is focused around when, where, whom, and how is key to a successful plan. Potential barriers need to be identified and addressed when the plan is not successfully carried out or the problem is not solved. The important elements of the process also involve the facilitator reviewing progress with the client to evaluate whether the plan is underway, whether it is having the desired impact, whether any more needs to be done in relation to the problem, and to understand the key areas which may need to be fine-tuned.

Step 7: Reviewing the process—The reviewing process plays an important role in the reflection and ongoing management of an individual who is attempting to problem solve. At this stage in the process, the reflection offers an opportunity to identify how effective the solution to the problem was and to identify whether the action plan worked, whether he or she would have done anything differently if he or she were to try again, and if any obstacles prevented the plan from happening. In essence, the problem-solving approach is a skill which helps an individual to gain confidence in dealing with a range of complex issues.

SUICIDE RISK AND SELF-HARM IN CORRECTIONS, PREVALENCE AND ESTIMATES

When compared to the general population, individuals involved in the criminal justice system are at increased risk of suicide and self-harm. Overall, death by suicide, suicide ideation, and self-harm are rare occurrences within the general population. Research indicates that when examined in the general population in 2014, death by suicide was the 10th leading cause of death in the United States, accounting for 42,773 deaths or 1.6% of all deaths. Worldwide, approximately 800,000 individuals die by suicide each year. Furthermore, 0.6% of individuals in the general population attempt suicide, and 3.3% experience suicide ideation at some point in their lives. Additionally, approximately 1–4% of adults and 13–23% of adolescents in the general population engage in self-harm without the intention to die.

When comparing these data from the general population to the data provided below, it is clear that suicide and suicide-related distress is more common among individuals involved in the criminal justice system. It should be noted that research about suicide-related behaviors suffers from a lack of consistent terminology to help define specific characteristics of these behaviors (e.g., the intent to die from the behavior); therefore, definitions

are provided for the purpose of this review. This entry discusses the prevalence of suicide ideation, nonsuicidal self-injury (NSSI), suicide attempts, and suicide deaths in corrections.

Suicide Ideation in Corrections

Suicide ideation refers to thoughts of ending one's own life. Research indicates that approximately 27% of male prisoners report current suicide ideation. Many studies have examined suicide ideation among prisoners in an attempt to examine the association between various psychological phenomena and suicide ideation; however, often times, these studies do not provide a prevalence estimate of suicide ideation. A similar problem exists with research that has examined suicide ideation among jail inmates. Despite this, it is possible to glean information about the prevalence of suicide ideation within correctional facilities from the percentages of inmates who attempt suicide and die by suicide. Within the general population, the majority of individuals who think about suicide do not go on to attempt or die by suicide. If this fact is extended to suicide within correctional facilities, a larger percentage of individuals in correctional facilities experience suicide ideation than the number of those who attempt or die by suicide.

Within community corrections (e.g., parole, probation, work release), 41% of individuals report experiencing suicide ideation sometime during their life. Other data suggest that 12.3% of individuals in community corrections report having serious thoughts about suicide. More specifically, on average, 9.7% of probationers report suicide ideation during their probation term over the last 12 months, which is about 2.7 times that of the general population. On average, 14.3% of female probationers and 7.8% of male probationers report suicide ideation during this time. These gender differences indicate that female probationers are 1.83 times more likely to report suicide ideation than male probationers and 3.76 times more likely to report suicide ideation when compared to nonprobationer females.

NSSI in Corrections

Self-harm is a broad term that does not specify intent to die from the behavior, and synonymous terms include *self-injury*, *self-injurious behaviors*,

parasuicide, and *undetermined suicide-related behaviors*, among others. NSSI is a more specific term that refers to intentional self-inflicted damage to one's body (e.g., cutting, burning, hitting) without intent to die. In general prison settings, prisons report that 2% of prisoners engage in self-injurious behaviors (intent to die not specified). Although this percentage may seem small, the majority of prisons indicate that self-injury occurs at least once per week. Other data indicate that 22.5% of adult prisoners in psychiatric units engage in NSSI. Moreover, 41.1% of female Canadian prisoners reported engaging in NSSI while in a federal correctional facility. The discrepancies in these data may indicate differences between what correctional institutions consider to be self-harm or NSSI versus inmates' self-reported data.

Within the New York jail system, there were 2,514 acts of self-injury between 2007 and 2011. The majority of these acts involved lacerations, followed by overdose, swallowing dangerous objects (e.g., razors), or asphyxiation. Of these self-injuries, 1,129 were not severe enough to necessitate a hospital transfer. In addition, approximately 28% of individuals who engage in self-injury engaged in this behavior more than one time. These numbers did not differ by age, sex, or criminal history. Among individuals involved in community corrections, approximately 14% had engaged in NSSI during their lifetime; however, there are not clear data to indicate what percentage of individuals involved in community corrections engage in NSSI during their involvement in community corrections.

Suicide Attempts in Corrections

Suicide attempt refers to nonfatal, intentional self-injury with the intent to die as a result. The determination of a suicide attempt can be challenging in many settings, given that inferring intent is not always straightforward. In addition, those in correctional settings may have a variety of reasons for indicating they have attempted suicide, some more genuine than others.

In the general population of the United States, there is an average of 25 suicide attempts prior to a death by suicide. Suicide attempts and other forms of self-injury are known risk factors for death by suicide, with research indicating that a

history of multiple suicide attempts is associated with greater risk of eventual death by suicide. Research has indicated that suicide attempts and death by suicide are 2–5 times more frequent in rural jails compared to urban jails. Research examining individuals in the Swedish criminal justice system who were being assessed for drug- or alcohol-related problems (including prison, probation, or remand) found that 21% had attempted suicide in the past. In this sample, 81% of those endorsing a history of suicide attempt were male. Additional research found that previous suicide attempt occurred in 7.7% of those in a community correctional sample who were still living, compared to 20.2% of those who had died of any cause (including, but not limited to suicide). Of the individuals involved in community corrections who report suicide ideation, 63% of them also report a suicide attempt history. Conversely, 37% of individuals within community corrections with a history of suicide ideation do not go on to attempt suicide. This further highlights that not all individuals who think about suicide will later attempt or die by suicide.

Suicide Deaths in Corrections

Suicide/death by suicide refers to death brought about by intentional self-injury with the intent to die as a result. Although suicide within jails and prisons has been declining since the early 1980s, it is still a leading cause of death in prisons and jails. Although it is the 10th leading cause of death in the general population in the United States, it is the third leading cause of death in prisons, and the second leading cause of death in jails. Jail inmates appear to be at increased risk of death by suicide when compared to prison inmates. Research suggests that jail suicides are approximately 3 times the rate of prison suicides (i.e., 47 suicide deaths per 100,000 inmates vs 14 suicide deaths per 100,000 inmates). Other estimates suggest that between 300 and 400 jail inmates die by suicide each year. In general, communities located in rural areas tend to have higher rates of death by suicide, and this is likely true of rural jails as well. More specifically, the suicide rate in the United States' 50 largest jails was approximately half that of smaller jails. Although risk factors for death by suicide during incarceration are covered in another

entry, it is noteworthy that 50% of individuals who die by suicide take their own life during the first week following incarceration. Additionally, there is a greater prevalence of suicide deaths among male prison and jail inmates when compared to female inmates. There is also a greater prevalence of suicide deaths among inmates younger than 18 years old and inmates who identify as White/Caucasian.

Individuals under community supervision or on probation also appear to have higher rates of death by suicide. Estimates have indicated risk up to 9 times that of the local suicide rate, depending on the location. Research conducted with probationers and prisoners in England and Wales found that 22% of probationers and 46% of prisoners who died during a 2-year period died by suicide or self-inflicted injury.

Limitations

Regarding Prevalence and Estimates of Suicide Risk and Self-Harm in Corrections

Data on suicide-related statistics have the potential to be biased due to inconsistent reporting. For example, a suicide may be labeled as accidental death or death due to unspecified causes. Further, if an inmate attempts suicide, is rushed to the hospital, and dies there, reports may not show that the prisoner died in prison. Similarly, there is inconsistent terminology within different correctional settings regarding suicide-related behaviors. Some settings may require self-injurious behaviors to be deliberate, a behavior that produces visible injury, injury that requires medical attention, an intent to die, or a lack of an intent to die. Some settings may not require some of these characteristics when defining self-injurious behaviors.

In addition, underreporting of suicide ideation and suicide-related behaviors should be considered among offender samples. Inmates who express suicide ideation to correctional staff may be placed on suicide precautions to increase observation of the inmate by correctional staff and limit access to means for self-harm. For example, inmates may be placed in *strip cells*, which are special cells where inmates' clothing and belongings are removed for safety against self-injury and

violence. Although these conditions may increase inmate safety, they may also deter inmates from disclosing suicide-related distress.

TECHNIQUES OF NEUTRALIZATION

The techniques of neutralization help explain why individuals sometimes engage in acts that they generally condemn, particularly criminal and other deviant acts. The techniques refer to a set of beliefs that justify or excuse such acts under certain circumstances. For example, individuals who generally condemn violence may believe that violence is justifiable if one is insulted or to protect the honor of one's gang. This entry describes the major techniques of neutralization and the research on them.

Development of the Techniques of Neutralization

The techniques were first described by Gresham Sykes and Davis Matza in 1957. Many prominent criminologists at that time argued that criminals, especially gang members, were part of an oppositional subculture that rejected conventional values and generally approved of acts such as violence, theft, and drug use. Sykes and Matza challenged this view, stating that most offenders generally condemn crime. This condemnation is reflected in the guilt and shame they often display over their criminal acts, as well as the admiration they frequently express for certain law-abiding people. And this condemnation reflects the fact that offenders are usually raised in families and associate with others who condemn crime. Sykes and Matza therefore try to explain how offenders are able to "violate the laws in which they believe."

Sykes and Matza argue that while acts such as violence and theft are generally condemned, they are justified or excused in certain circumstances. This is true of the legal system and most people in society. Violence, for example, is justified in combat situations during war. Sykes and Matza argue that offenders employ a broad range of justifications and excuses, including many that are not recognized by the legal system or accepted by most others. In particular, they state that offenders are more likely to accept five techniques of neutralizations or beliefs that justify or excuse crime in certain circumstances. These techniques are said to be learned from others, such as friends.

Description of the Five Techniques

Individuals employing the technique known as *denial of responsibility* claim that they are not responsible for their criminal behavior. Their behavior is attributed to such things as accident, intoxication, unloving parents, or growing up in poverty. Those employing *denial of injury* claim that their crime does not cause any great harm. For example, they claim that they were only *borrowing* the car they stole or that the store owners from whom they steal have insurance to cover the loss. Those employing *denial of the victim* state that the victim deserved it. They claim, for example, that the victim of their violence started the fight or that the storeowner from whom they stole cheats others. Those employing *condemnation of the condemners* claim that those who would condemn them engage in objectionable behavior.

The police, for example, are said to be *crooked* and abusive. And those employing *appeal to higher loyalties* claim that their crime was committed to help friends, family, or others. Certain additional techniques have been suggested by others, including Albert Bandura in his description of the techniques for moral disengagement.

Sykes and Matza summarize their five techniques of neutralizations in the following phrases: “I didn’t mean it,” “I didn’t really hurt anyone,” “They had it coming to them,” “Everybody’s picking on me,” and “I didn’t do it for myself.” Sykes and Matza acknowledge that these techniques are often used as after-the-fact rationalizations, in an effort to alleviate guilt and avoid blame and punishment. But they state that these techniques are also used before individuals engage in crime and that they help make crime possible by neutralizing one’s belief that crime is wrong or immoral in their particular circumstances. The techniques, it should be noted, are closely related to certain other theories of crime and deviance, most notably Albert Bandura’s 1990 description of the techniques for moral disengagement.

Research and Evidence

Research indicates that offenders are somewhat more likely to accept the techniques listed earlier than are nonoffenders. Furthermore, certain studies that follow individuals over time indicate that individuals who accept the techniques at one point in time are more likely to engage in crime at a later point. More research is needed here, however. The techniques have been applied to a wide range of crimes and deviant acts, including theft, violence, drug use, white-collar crime, genocide, cheating, and gambling. These techniques have also been employed in studies of consumer behavior and business ethics. And the techniques have informed several crime prevention programs, which attempt to challenge the neutralizations that offenders often employ for their crimes.

At the same time, it should be emphasized that these techniques are just one of several causes of crime. It has been argued that if the techniques are to cause crime, certain conditions must hold. Individuals must believe that they are in situations where the techniques are applicable. For example, those who believe that violence is a justifiable

response to insult must believe that they have been insulted. Also, individuals must be motivated to engage in the offense. The neutralizations do not motivate crime but rather make crime possible by reducing the individual’s condemnation of particular criminal acts. In addition, it has been argued that the neutralizations are not simply learned from others. They often emerge after individuals have engaged in criminal acts, as individuals seek to rationalize their behavior. But once the neutralizations emerge, they pave the way for further crime. Finally, some evidence suggests that certain hardcore offenders may not need to employ the techniques because they do not generally condemn many criminal acts. As such, they have nothing to neutralize.

TELEHEALTH

According to the National Telehealth Policy Resource Center, telehealth (or telemedicine) refers to a collection of health-care services that are delivered remotely using technology. Services that are commonly provided via telehealth include, but

are not limited to, dentistry, psychiatry, counseling, physical and occupational therapy, chronic disease monitoring and management, and education and training. The mode of providing such services generally falls into one of four categories: (1) live two-way interactions (e.g., videoconferencing, webcams), (2) store-and-forward transfers (e.g., prerecorded videos, digital images), (3) remote patient monitoring (i.e., provider access to patient data at multiple locations), and (4) mobile health (e.g., targeted text messages, personal digital assistants). Telehealth was developed to help bridge the gap between the supply and demand of quality health care, particularly for individuals who live in difficult-to-access regions, by circumventing many of the barriers associated with in-person delivery. Telehealth is not intended to replace traditional in-person contact, as there are obvious advantages to seeing a client face-to-face while in the same physical location. However, telehealth can serve as a supplement to in-person contact or as a stand-alone option when in-person contact is not feasible or available.

One of the first attempts at remote service delivery within a prison system began in 1974 at the University of Miami, where physicians provided medical care to inmates at three different facilities using microwave transmission (i.e., information transmitted through radio waves). This method of service delivery did not persist due to high operation and maintenance costs. With advancements in technology, telecommunication-based health care reappeared in corrections during the 1990s and continued to rapidly increase over the next several decades. In 2004, 26 states operated telehealth programs that reached over 400 correctional facilities across the United States. By 2015, all 50 states operated telehealth services (with a majority offering some level of insurance coverage). About 20% of all telehealth applications are estimated to involve correctional clientele. Most relevant to this encyclopedia on criminal psychology is the use of telehealth to deliver psychological and legal services in the criminal justice system.

Why Telehealth in the Criminal Justice System?

Beginning around the mid-1980s, drastic increases in the adult incarceration rate created a demand

for prison expansion. This issue led to the construction of correctional facilities across the United States, but particularly in rural regions, where prisons and jails were also seen as a strategy for reviving employment rates and increasing local government revenue. Consequently, rural prison expansion became big business. However, correctional facilities generally experience many challenges when it comes to providing health-care services to inmates. The prospect of professional burnout, low paying incentives, and the remote rural location of many jails and prisons can lead to scarce, untimely, and inconsistent service delivery.

The rising cost of health care also inhibits access to services for many inmates who are in need. Even in the late 1990s, the cost for an off-site service provider was estimated to be as high as US\$1,000 per inmate visit. Health-care costs include not only the actual services rendered but also travel expenses and salaries for correctional personnel who need to accompany inmates on visits. In addition, the absence of competition among *specialty* providers (e.g., forensic psychologists, counseling for inmates who are HIV-positive, sex offender treatment, early parole assessments), particularly in rural areas, can increase the price of services well above average.

Because of financial and logistical challenges, corrections departments began to rely on contracts with medical centers and university hospitals to increase inmates' access to health care, including mental health services. Although this may seem like a viable remedy, profit motives can sometimes outweigh incentives for quality care, thereby compromising ethical standards of practice. In addition, community-based contractors, who generally lack an understanding about the constraints of correctional environments, may offer treatment recommendations that are inconsistent with security and management needs; this issue often translates to ineffective care and rehabilitation for inmates. Contracting to outside providers also does not alleviate the expense associated with traveling either in or out of a remote facility. Thus, there became a need for an alternative to traditional in-person methods of providing state-of-the-art health care to inmates.

Telepsychology

In 2013, John C. Norcross, Rory A. Pfund, and James O. Prochaska projected that the integration of technology into mental health sectors would be the largest growing trend in psychotherapy by 2022. Its expanding popularity has also been demonstrated in mainstream psychological publications such as the *Monitor on Psychology* and *GradPSYCH*. Also in 2013, the dramatic increase in the use of the so-called telepsychology prompted the American Psychological Association to develop specialty guidelines for practitioners. The use of telecommunication systems for providing psychological and behavioral services is now applied to a broad range of psycho-legal and correctional contexts. For example, telepsychology makes it possible for a well-renowned psychologist in New York City to provide services to a federally detained prison inmate located in rural Missouri.

The most salient benefit of using telepsychology in criminal justice settings is heightened security and safety for the inmates, staff, and the public. When inmates are transported to off-site agencies, there is an increased risk of escape and harm to staff or civilians. Conversely, in addition to being costly and time-consuming, it can be intimidating and potentially dangerous for external providers to enter an unfamiliar facility. Telecommunication systems instead allow inmates to receive services within the confinements of secure perimeters. Another advantage of using telepsychological services for inmate populations is the potential for reduced wait times that result from eliminating several steps (e.g., transportation to external agencies, initiating security procedures to move in or out of a facility, hiring more mental health staff to provide on-site care) that are involved in connecting inmates to necessary services. Furthermore, the pool of available and qualified clinicians may increase if the delivery mechanism is more convenient. Efficiently and effectively responding to requests for mental health services may increase inmates' trust in and adherence with the mental health system. Improving access to appropriate psychological and behavioral interventions for those in need could have further unanticipated effects on correctional employees who will be able to focus on running a safe facility rather than attending to custody and

disciplinary problems that are secondary to mental health disturbance.

The use of telepsychology may also create greater continuity of care across various stages of the legal and rehabilitative process. For example, inmates who are being discharged from a forensic mental health hospital to a secure correctional facility could have their first few sessions with continuing care providers while still at the medical center. Similarly, telecommunications can assist correctional psychologists in coordinating community resources (e.g., parole officers, medical providers, job supervisors) for inmates preparing for release. Special needs cases requiring intensive care that combines psychological and medical services (e.g., substance abuse treatment and infectious disease specialists for inmates who are HIV-positive) can also be better accommodated through telepsychological approaches. Moreover, telepsychology offers the ability to involve prosocial others from the community in the inmate's treatment. Family therapy, including parenting counseling, would allow significant others to participate alongside their incarcerated partner from a remote location. This capacity may be particularly beneficial for detained youth offenders who often require comprehensive treatments that involve a network of caregivers, school officials, peers, and other agencies to promote positive behavioral changes.

Despite the possible benefits of telepsychology, mental health providers themselves have often been cited as the most resistant to using remote delivery mechanisms. Many professionals hesitate to embrace telepsychology due to the geographical distance that is placed between themselves and their clients. Psychologists are typically trained in models of therapy that assume clients will receive in-person services in the same room; this pairing of interpersonal and physical space has come to define the therapeutic relationship as a tangible attachment. The remoteness of telepsychology leads many psychologists to fear losing emotional connectedness with their clients; however, research suggests that this fear is more salient for the provider. For example, a study with male prison inmates found no significant differences for telepsychology versus in-person services on ratings of client satisfaction, perceptions of therapeutic alliance, or post-session mood. Relatedly, another

study found that jail staff perceived technology-based services as easily integrated into their routine practice of care and institutional security. Research has further shown that psychological and forensic assessments can be reliably conducted through telecommunication systems even though evaluators felt less satisfied with the video interview format.

As of 2016, the knowledge base regarding long-term treatment outcomes for criminal offenders was promising but limited. The few treatment-based studies that were available in the literature tended to lack strong research methodology. In a 2015 meta-analytic review of videoconferencing-based mental health services for criminal justice and substance-abusing clients, only five of 14 topic-relevant studies were identified as having adequate scientific integrity, which was determined by a study's use of random assignment or inclusion of a demographically similar comparison group. Of those five, just two examined treatment outcome variables in response to a psychotherapy intervention; the others focused on assessment reliability or service satisfaction. With the increased social and cultural reliance on technology in general, it was around this time that criminal and forensic psychologists began to focus on expanding the empirical support for operating treatment-driven telepsychology networks.

Telelaw

Applications of technology are also becoming more prevalent in the modern courtroom. The first documented systematic application of telecommunications in a legal setting occurred in 1972 when an Illinois court began conducting bail hearings via videophone. Since then, the virtual courtroom has expanded to include a number of procedural tasks such as attorney-client consultations, preliminary arraignments, oral argument, testifying in open court, and judicial rulings.

The use of telelaw in the courtroom has largely focused on witness testimony. Earlier attempts to provide remote witness testimony using videoconferencing sparked some concern that the trier of fact would perceive these witnesses as less credible or truthful than witnesses who were physically present in the courtroom. Much of this concern logically stemmed from inherent technological

glitches (e.g., audio delays) or interpersonal barriers that might interrupt the natural reciprocity and flow of conversation. In fact, research suggests that maintaining eye contact with jurors, which may be disrupted or even impossible through the use remote technologies, can improve perceptions of a witness's credibility. One study conducted in 1998 showed that mock jurors rated child witnesses who testified by video feed as less credible than in-court witnesses. Of note, the same group of study participants did not differ on their perceptions of the defendant's culpability in the case, suggesting that witness credibility was either not a significant factor in mock jurors' decision-making or that child witnesses were seen as believable enough to assign a guilty verdict. In 2005, another group of researchers in Sweden similarly showed that mock jurors who observed a witness testify remotely rated the witness's appearance and trustworthiness less positively than those who observed the witness testify in-person. Findings from this study further indicated that in-person observers incorrectly believed they could better recall the witness's statements following testimony than the video observers. Interestingly, participants in this study were also asked to determine whether or not the witness was lying on the stand; mock jurors' accuracy in identifying truth-tellers versus liars was not effected by modality of testimony. Overall, this study indicates that, while credibility was diminished for remote witnesses, the quality and quantity of information conveyed was unaffected.

As noted earlier, the application of real-time, remote technology in the courtroom has also begun to include tasks designated to forensic mental health professionals (i.e., psychologists and psychiatrists), such as assisting the trier of fact in making sound decisions about a defendant's competence to stand trial. While there is some evidence that expert opinions regarding a defendant's competence to proceed are not greatly altered when comparing evaluations conducted remotely and in person, it remains unclear how these experts would be perceived in the courtroom if they testified remotely about their opinions. There is a line of research suggesting that the perceived likability and competence of an expert witness—which may include factors beyond the expert's professional qualifications and credentials such as

gender, dress, general demeanor and mannerisms, and eye contact—can affect the extent to which jurors incorporate the expert's opinions into their ultimate legal decision. That is, regardless of how expertly crafted an evaluation is, the extent to which the information is helpful to the court can depend heavily on how the expert comes across during testimony. As of 2017, no research had examined whether telelaw affects the perceived credibility of expert witnesses.

Despite the limited evidence supporting the use of audiovideo to deliver live testimony, it is currently admissible in many state jurisdictions and the federal government. Some jurisdictions have even upheld the use of less secure services like Skype (e.g., *Marriage of Swaka*, 319, P.3d 69 [2014]) to transmit witness testimony. In addition to witness credibility, research is beginning to examine other uses of telelaw. For example, in evaluating attorney–client consultations, Brendan McDonald and colleagues found little difference in defendant and attorney satisfaction ratings across remote and in-person contacts. Potential benefits for expanding the use of telecommunications, like videoconferencing, within the legal system include cost savings, risk reduction (e.g., not having to transport defendants from jail to the courtroom), greater access to justice (e.g., by increasing defendant or litigant participation in proceedings), speeding up the judicial process, and general convenience.

Implementing Telehealth in the Criminal Justice System

Limits to confidentiality associated with the use of telehealth constitute a major concern for health-care professionals and correctional policy makers. Because clients in correctional facilities should not be left unsupervised, particularly with expensive technological equipment, it may be necessary to have at least one staff member present or located at a nearby location during treatment sessions or medical appointments. Properly securing equipment in protective material such as Plexiglas and setting up a quick and easy way for off-site providers to contact security staff may eliminate the need for in-person supervision. Other possible consequences of telehealth-based interventions for

inmates include impromptu equipment failures; inaccuracies in diagnosis due to physical, emotional, and cognitive disturbances that cannot be captured through video monitoring; resistance among inmates with personality or thought disorders; and delayed team-based treatment decisions due to the involvement of multiple providers who may be located at multiple sites or even across time zones.

To mitigate some of these challenges, consideration should be given to the facility's available resources (e.g., off-site providers willing to offer expertise, funds to purchase and maintain equipment, space to set up and secure the system) prior to establishing a telehealth program. Once a correctional agency elects to initiate a telehealth program, systematic guidelines, including initial referral procedures, strategies for troubleshooting technical difficulties, and policies for handling emergencies should first be established. Internal staff and outside providers should then receive training on these institution-specific policies. Lastly, all relevant parties, such as psychologists, correctional officers, mental health counselors, medical personnel, and the client should spend time building a working relationship, clarifying role expectations, and developing and monitoring mutual goals.

TERRORISM: INTERNATIONAL PERSPECTIVES

The phenomenon of terrorism has featured in history since the *Reign of Terror* during the French Revolution (1793–1794) but has changed considerably since then. Therefore, a term that was used originally to describe governmental actions is now mostly used to refer to actions committed against civilians and perpetrated by individuals or groups not directly linked to a state. An examination of the historical evolution of terrorism reveals not only a change in the modus operandi of terrorist organizations but also a shift in the international dimension of the phenomenon. After discussing issues associated with defining terrorism within an international framework, this entry focuses on the international efforts, including laws and models, to counter terrorism.

Defining Terrorism

The universal condemnation of terrorism since its introduction to the international agenda via the League of Nations in 1934 has not contributed significantly to the elaboration of a generally acceptable definition within an international framework. The United Nations (UN) General Assembly has played a central role in addressing some of the specific manifestations of international terrorism, such as airline hijacking, unlawful seizure of aircraft, and hostage taking, via the adoption of resolutions and conventions.

According to UN General Assembly Resolution 49/60, titled “Measures to Eliminate International Terrorism” (adopted on December 9, 1994), terrorism is described as “Criminal acts intended or calculated to provoke a state of terror in the general public, a group of persons or particular persons for political purposes are in any circumstance unjustifiable, whatever the considerations of a political, philosophical, ideological, racial, ethnic, religious or any other nature that may be invoked to justify them.” Although the relevant UN anti-terrorism treaties criminalize particular manifestations of terrorism, they do not criminalize terrorism generally. Rather, they impose a duty on member states to render the said conduct an offense under their national laws and then prosecute or extradite the alleged offender.

The search for a universal definition of terrorism has been the subject matter of much academic work. Yet, it has not been possible to provide a clear and comprehensive definition, as there is disagreement in academic discussion as to the elements to be included in a definitional framework. Despite the lack of an accepted universal definition of terrorism, there seems to be a general agreement that most explanations typically involve reference to certain notions—more specifically, that terrorism refers to unlawful or illegitimate violence against deliberate targeting of civilians, which creates a state of fear in the general public for the achievement of political or ideological goals.

The definitional issues related to terrorism continue to be relevant. However, since the attacks of September 11, 2001, the international agenda has developed toward concerns related to responses to terrorism, including the use of armed force against terrorism, preventive mechanisms related to domestic banking and financial institutions, and sharing of information and other binding forms of interstate cooperation.

International Counterterrorism Efforts

The international dimension of terrorism from the 1960s onward has led to the birth of a number of international instruments. These international instruments encompass different manifestations of violence upon civil aviation (e.g., 1963 Tokyo Convention on Offences and Certain Other Acts

Committed on Board Aircraft), civil maritime navigation and sea-based platforms (e.g., 1988 Rome Convention for the Suppression of Unlawful Acts Against the Safety of Maritime Navigation), and attacks upon persons, including hostages, diplomats, and other internationally protected persons (e.g., 1973 Convention on the Prevention and Punishment of Crimes Against Internationally Protected Persons).

The establishment of the Ad Hoc Committee of the UN General Assembly (G.A. Res. 51/210) on December 17, 1996, has further elaborated terrorist bombing and terrorist financing conventions, followed by the elaboration of two other agreements: one on nuclear terrorism and a comprehensive convention on terrorism. In general, the UN anti-terrorism instruments place emphasis on suppression rather than on prevention of terrorist activity.

The UN anti-terrorism conventions establish a framework that encourages member states to assist each other in the global fight against terrorism and obliges them to either punish or extradite those responsible for the offenses prescribed therein. It should be reiterated, however, that the anti-terrorism international instruments do not themselves impose the duty to extradite the offender; rather, such duty is placed within the general extradition framework contained in various bilateral and multilateral extradition treaties.

The Role of International Law in the Fight Against Terrorism

International law plays a central role in the fight against terrorism as evident by the growing body of international treaties applicable to the crime of terrorism. As already outlined, the main benefit of this body of law is that it creates a framework within which national counterterrorism activities may take place, such as cooperation among states in preventing and suppressing terrorism. Likewise, the major effect of such international legal instruments is that they prescribe certain obligations to member states to criminalize certain terrorist activities under their national legal systems and encourage the judicial authorities of member states to initiate criminal proceedings.

As noted earlier, the UN is responsible for the creation of international treaties and resolutions,

and it does so via the Security Council, which is authorized by the Charter of the UN to adopt binding resolutions. An indicative example is Resolution 1373, which was adopted in 2001, after September 11. According to its provisions, states are obliged to freeze the financial assets of those who commit or attempt to commit acts of terrorism and their supporters, to deny them travel or safe haven, and to prevent terrorist recruitment and the supply of weapons. Furthermore, this resolution obliges countries to afford one another *the greatest measure of assistance* in investigating and prosecuting terrorist acts and calls upon them to sign and ratify the international conventions and protocols against terrorism. Moreover, Resolution 1540, which was adopted in 2004, obliges states to refrain from supporting by any means nonstate actors that attempt to develop, acquire, manufacture, possess, transport, transfer or use nuclear, chemical, or biological weapons and their delivery systems.

However, the approach of adopting international legal instruments is not without shortcomings. Almost all of the international instruments have been adopted as a response to major terrorist attacks and thus are reactionary rather than preventive in nature. In addition, the measures adopted by the Security Council require the existence of national legal mechanisms to implement them at a domestic level. However, the effectiveness of the Security Council's measures can be affected negatively if states are unwilling to implement the measures domestically due to their own national interests. Thus, reliance on domestic implementation might disadvantage the fight against terrorism as the enforcement of the international legal framework is challenged.

Use of Force Against Terrorism

The right of self-defense is one exception to the UN Charter's general prohibition on the use of force. As stated in Article 51 of the Charter: "Nothing in the present Charter shall impair the inherent right of individual or collective self defense if an armed attack occurs against a Member of the UN, until the Security Council has taken the necessary measures necessary to maintain international peace and security." Following September 11, the United States responded by exercising its right to

self-defense and employed the use of force as a counterterrorism method. The U.S. response raised a number of questions in relation to the existing international framework and the suitability of the use of force in the case of terrorism. Some have argued that the label *terrorism* could be abused by powerful states in order to justify military actions against another state (e.g., a state that might have links to or support terrorist organizations). Therefore, the international community via the UN and academic and political circles appears skeptical with regard to the application of the use of force as a counterterrorism model.

National Counterterrorism

The national counterterrorism module relies on a framework of criminal justice that potentially may protect democratic values while fighting terrorism at a national level. It seeks to ensure the legitimacy of the legal process when dealing with those responsible for terrorist offenses and places much emphasis on human rights considerations. However, evaluating what makes an effective strategy poses methodological difficulties, and it has been observed that because of the varied nature of terrorism and subsequent responses, a universally applicable methodology of analysis is not possible. It has been argued that a holistic strategy, containing elements of suppressive and preventive actions, could be effective. An example of a holistic strategy to combat international terrorism is the UK CONTEST strategy, which contains four pillars: *Pursue*, in order to stop terrorist attacks from taking place; *Prevent*, in order to stop people turning to terrorists or supporting violent extremists; *Protect*, in order to offer protection against terrorist attack; and *Prepare*, in order to mitigate the impact of an attack when it cannot be stopped and offer assistance in the aftermath. The complexity of contemporary terrorism, with its multifaceted and evolving nature, suggests that an effective counterterrorism strategy should encompass a combination of all available counterterrorism models in order to provide a coordinated and holistic answer to the challenge of terrorism.

TEXAS SYNDICATE

In the mid-20th century, around the time of the passage of the Civil Rights Act of 1964, radical inmate gangs appeared in state prisons in California and Texas. In 1992, the U.S. Supreme Court recognized the existence of six major prison gangs in the California Department of Corrections: Mexican Mafia, Nuestra Familia, Black Guerrilla Family, Aryan Brotherhood, Nazi Low Riders, and Texas Syndicate (TS). The Court cited (vs. street gang members in prison) the virtual absence of non-criminal, nondeviant activities by its members as a distinguishing feature of prison gangs. The Court wrote that prison gang members are violent zealots devoted to acting out as prison gangsters while proclaiming and advocating a separatist, racist creed and that prison gang members are violent, racist murderers who lie, cheat, and steal.

In December 2014, the United States had approximately 1,800 state and federal prisons. Federal and state prisons held 1.5 million convicted felons from among the 317 million people

in the United States. There are approximately 3,200 local and county jails. Federal prisons confine inmates convicted of offenses that violate the U.S. Constitution. State prisons confine felons convicted of offenses under state jurisdiction. These include, among numerous others, homicide, assault and battery, and burglary. In 2011, the National Gang Intelligence Center estimated that up to 15% of prison inmates are gang members, which include prison gangs, street gangs, and motorcycle gangs.

Prison gangs have had a profound effect on the U.S. state and federal prisons. Yet they are hidden behind high walls and razor wire fences. The public's knowledge of prison gangs' criminal behavior inside prisons depends on outside investigators' access to official prison records and opportunities to interview prison staff and prison gang members. To grasp the complexity of conducting prison research necessary to describe accurately prison gangs as a disruptive force in state and federal prisons, this entry elucidates social researchers' difficulties studying prison gangs inside prisons, pressures of social life among prison inmates and how it contributes to gang affiliation, and the TS's criminal behavior, inside and outside prison.

Barriers on Prison Gang Research

Social researchers' opportunities to study prison gangs operating inside prisons have been limited by strict correctional systems' policies limiting nonemployees' access. Prisons are law enforcement agencies, which must protect the confidentiality of official records and inmate privacy. Social researchers cannot walk into a police department and request confidential criminal or administrative records.

Prison inmates are outside public view and vulnerable to researchers' abuse and exploitation. Social research inside U.S. prisons requires strict scrutiny of the nature of research; researchers' proposed methods of data collection; the nature of the data collected, such as inmate and staff interviews or a review of prison records; a description of data analysis procedures; a statement of the ways research results will be disseminated; and assurance that research subjects' anonymity and confidentiality will be protected.

Researchers must pass two levels of strict review. First, researchers must submit a detailed research application to a correctional agency. Upon receipt, the prison research committee can quickly read the proposal and deny it without explanation. If the research committee reviews and approves the application, there are additional levels of scrutiny. An approved research application must then be further approved by the senior-most administrative official, a director, or a commission of corrections. If researchers obtain approval, the warden of the prison where research will be conducted must then consent, as well. Then researchers must pass through another level of scrutiny imposed by their university.

Next, researchers must comply with research regulations governed by the U.S. Office of Human Research Protections, a federal agency that stipulates guidelines and requirements that protect research with human subjects. These regulations are implemented and monitored by a university's Institutional Review Board, a panel of experts convened to ensure that research complies with federal regulations. These regulations ensure that human subjects' rights, welfare, and well-being are protected. Even if researchers pass a research review by a corrections agency's and their university's Institutional Review Board and obtain permission from a director or commissioner of a state corrections agency, the warden of a prison where research was intended to occur can refuse to permit researchers from entering the prison. If that occurs, there are no appeal procedures. If a warden grants researchers access, prison staff and inmates can refuse to be interviewed. If inmates or staff agree to be interviewed, they have the right to terminate an interview at any time and refuse to answer questions without an explanation.

It can be uncertain whether inmates with or without a prison gang affiliation will agree to be interviewed. If prison gang members comply, they might be subject to injury later if fellow gang members believe they have divulged information on their gang's involvement in violent and nonviolent misconduct (e.g., drug distribution, murder, or assault on inmates and staff). Revealing that information (known as *snitching*) to researchers can violate a prison gang rule, resulting in an inmate snitch's death.

Prison Life: Stress of Inmate Social Relations

Prisons have an intense social environment. Lonely, scared, intimidated, newly admitted inmates are novices to prison life who must quickly learn the rules of social interaction among inmates and between inmates and staff. New inmates often seek companionship to quell feelings of loneliness and gain a sense of safety. In prison, safety in numbers can quiet feelings of fear. An inexperienced inmate might seek companionship with members of a prison gang, and this can ultimately lead a new inmate to commit acts of violence ordered by prison gang leaders.

Inexperienced inmates find themselves caged in an environment under never-ending visual scrutiny by staff and fellow inmates. Inmates can be subject to body pat searches by staff at any time for any reason. Constitutional rights that protect free citizens from unlawful search and seizure do not apply in prison. If inmates are housed in cells, they live behind steel bars in cramped quarters shared by another inmate, who is a stranger until they meet face to face.

New inmates must learn that what they say and how they say it can have adverse consequences. Their facial expressions when speaking and demeanor when approaching other inmates and staff are forms of communication inside (vs. outside) prison, and these can send the wrong signal. How inmates wear their clothing, stride among other inmates, and look at other inmates can violate unwritten rules of inmate social interaction. Outside prison, the greeting *good morning* can bring a smile. Inside prison, however, that same greeting can signal a new inmate's weakness and vulnerability and convey to veterans of prison life that a new inmate can be manipulated or is an easy mark for the theft, for example, of new sneakers or a radio.

In men's prisons, social relationships have terms, such as *tips*, *cars*, *homeboys*, *crime partners*, and *yardies*. In women's prisons, social relationships have different terms. *Tips* are two or three inmates who regularly hang out, chat, and sit together at mealtime. County *cars* comprise inmates who resided in the same county before they were imprisoned. A county car can include dozens of inmates, some of whom form tips

within the car. In prisons where staff have cracked down on prison gangs, car affiliations can serve a similar purpose, conveying a sense of safety and protection in the event of interracial hostility.

Homeboys are inmates who knew one another on the street or resided in the same neighborhood before they were imprisoned. Homeboys can be members of the same car. *Crime partners* are inmates who committed crimes together. Crime partners can be homeboys and/or members of the same car. Outdoor recreation areas are termed *yards*. *Yardies*, therefore, are inmates who spend time together on the yard, jogging, weightlifting, walking, playing basketball, or just hanging out. Inmates in tips or cars who were crime partners or homeboys might also have been members of the same street gang and continue their gang association inside prison.

These relational terms identify instrumental social ties, which afford inmates companionship and a sense of safety in numbers. Researchers have reported that inmates who were not gang members outside prison oftentimes seek protection in a prison gang. An increase in a prison gang's membership creates double bind for its members. As a gang's membership increases, so does its members' sense of safety, but increasing membership can lead to more scrutiny by prison staff or a need to defend the gang from competing gang members who feel threatened by the expanding membership of a rival gang.

TS: Inside a Violent Prison Gang

Origins

The TS appeared in 1958 at Deuel Vocational Institute in California. A tattoo, the letter T superimposed on an S (for TS), inked into individuals' forearm identified its members. Several decades later, in response to harassment from racial and ethnic gangs, prison authorities recognized the TS's appearance at California's Folsom State Prison in the early 1970s and at San Quentin State Prison in 1976. In California prisons, TS members have attacked, killed, and severely injured inmates and staff. The California Department of Corrections reported that the TS was one of several prison gangs, namely, the Mexican Mafia, Aryan Brotherhood, Texas Mafia, Self-Defense Family, Pistoleros Latinos, Nuestro Carnales, Crips, and

Mandingo Warriors, responsible for prison murders and armed and unarmed assaults.

All TS members were not Texans. The TS admitted individuals of Mexican background, even if they were Californians. Over years of imprisonment, TS members native to Texas and California formed alliances. Upon release, California members chose to move away from home communities, where they had trouble, to start again in another area. Texas members returned home. In Texas, they reaffirmed mutual affiliation and continued criminal activities. Texas state and federal law enforcement agencies were aware of TS members' extremely violent behavior.

Organization

A Texas Gang Threat Assessment in August 2015 by the Texas Department of Public Safety reported that the TS had an estimated 3,400 members. Prison gang investigators have testified in court that the TS is the most highly structured, aggressive, and violent prison gang. Its members adhere to a strict constitution of 22 rules that offer members protection inside prison and promise wealth and brotherhood outside prison. In exchange, members are obligated to return a share of their criminal proceeds to the gang. Its members have shown strong loyalty. TS ethos requires that the gang come before family, church, and everyone else. Rule violations can result in the gang issuing a death warrant calling for a rule violator.

The TS has a hierarchical structure, with a president and vice president, as well as an appointed chairman in each local area (in a prison or in the community). The chairman watches over that area's vice chairman, captain, lieutenants, sergeant at arms, and soldiers. Lower ranking members perform the gang's criminal activity. When members outside prison are arrested and convicted and returned to prison or when imprisoned members are transferred between prisons, the president and vice president retain their rank; others lose their rank and function as soldiers.

Crime Outside Prison

TS members have criminal convictions predating their gang affiliation inside prison, which can

include murder, kidnapping, and armed robbery. In the community, the TS had been engaged in human trafficking, including forced labor trafficking and commercial sex trafficking (i.e., forced prostitution among adults and minors).

TS branches have been reported in Austin, Corpus Christi, the Dallas Fort Worth area, and Rio Grande Valley. Branches are called *cells* and have a strict internal hierarchy and generally act independently of one another. Members in one branch can request members of another branch to commit murder. A federal indictment described a Dallas branch ordering a member of the Rio Grande Branch to murder a member of that branch who mishandled a drug deal. Federal prosecutors charged TS members under the Racketeer Influenced and Corrupt Organizations Act, which forbids any person associated with any enterprise from associating with activities that affect interstate or foreign commerce. Federal prosecutors successfully proved that the TS had a hierarchical structure, a chain of command, fixed roles for group members, rules and regulations, and disciplinary procedures. TS members found guilty were subject to Racketeer Influenced and Corrupt Organizations Act penalties that vary depending on the facts of the crime. The Federal Bureau of Investigation has reported on TS's association with Mexican drug cartels, which indicates a continuation of TS Racketeer Influenced and Corrupt Organizations Act activities.

Crime and Punishment Inside Prison

Rarely are crimes committed inside prison adjudicated under state or federal criminal code. Prison-based crimes, even murder, are given a ruling under a prison system's disciplinary policies. Minor prison infractions can result in restrictions on recreation or access to a prison commissary (a store that sells, among other commodities, chips, powdered soup, and coffee). Serious misconduct, such as murder and drug distribution, can warrant severe sanctions, including an enhanced prison sentence and many years locked down 24 hr a day in a supermaximum security prison, which state and federal correctional agencies use to manage violent gang members.

Security Threat Groups (STGs) Management

The TS has continued its prison drug dealing and killings and its assault on staff and inmates and has expanded its criminal activities into the community. The TS and other prison gangs threaten inmate and staff safety and erode prison security. The label STGs has been applied to prison gangs' persistent threat to prison management and quality of life by instigating and engaging in violence, drug selling, extortion, and murder. In the mid-1980s, STGs were responsible for 50% of prison management problems. Management problems go beyond responding to violence. In federal prisons, inmates, including prison gang members, are assigned to work assignments, ranging from meal preparation to electrical and plumbing repairs to sweeping and mopping floors to furniture manufacture. In a prison with 1,500 inmates, for example, inmate cooks must prepare close to 5,000 meals every day. If an inmate assigned to food preparation has a fight and then spends 2 weeks in disciplinary segregation, other inmates' workload increases and food preparation efficiency slows.

Monitoring STG members' behavior, investigating prison misconduct (crime), and sanctioning those found guilty of misconduct belong to the members of the custody department. Custody personnel act as the prison's police department with a chief, lieutenants, sergeants, and patrol officers (often called *guards*), who are known as *line staff*. Custody departments' data systems store photographs of prison gang members, along with their history of prison misconduct and criminal court convictions. Custody line staff are trained institution security officers, who are experts in monitoring inmates, especially the most potentially violent inmates.

Line officers work among inmates, enforce inmate misconduct rules, keep a close watch on inmates in cell blocks and dormitories, and conduct body pat downs searching for weapons and contraband (drugs). Sergeants and lieutenants ensure that line officers who work day-to-day among inmates are familiar with prison gang members' identity and aware of the danger they pose to the safety of prison personnel and inmates. Custody personnel can embolden gang members to leave gang life behind. Withdrawing from gang

activity, however, can be dangerous. Those who choose to withdraw reside in special, hypersecure housing quarters and are subject to monitoring systems that keep them safe.

Senior custody officials include investigators, trained personnel (prison detectives) who specialize in prison gangs and investigate violent behavior committed by gang and nongang members. Investigators verify inmates' gang affiliation and compile information on gang members obtained from state and federal law enforcement agencies. They also notify local police departments when prison gang members are scheduled to be released and returned to the jurisdiction where they were convicted.

Family-Based Prison Gang Prevention and Intervention

Texas prisons identify 12 STGs: Aryan Brotherhood of Texas, Aryan Circle, Barrio Azteca, Bloods, Crips, Hermanos De Pistoleros Latinos, Mexican Mafia, Partido Revolucionario Mexicanos, Raza Unida, Texas Chicano Brotherhoods, Texas Mafia, and TS. A document published by the Texas Department of Criminal Justice implores the friends and families of inmates to advise their imprisoned loved ones to stay away from STGs. The document explains the dangers of gang involvement and restrictions placed on gang members. STG members are disallowed from participating in academic and vocational activities and holding an inmate job. This restriction limits social interaction and, in turn, limits possible intergang hostility. STG members are assigned to administrative detention cell blocks where they live locked down 24 hr a day. STG members are denied a full range of privileges, including noncontact visitation with family and friends. Contact with fellow inmates is limited as are opportunities for participating in recreation programs and outdoor recreation (e.g., walking the prison yard). These are small, but important, pleasures inmates enjoy. Sanctions on known STG members remove those small pleasures and make a difficult life in prison even worse.

THEORETICAL MODELS OF VIOLENCE AND AGGRESSION

It has been said that any person can become aggressive or violent under certain circumstances (e.g., when at war, protecting oneself or loved ones). Violence can be collective (i.e., between nations or groups), interpersonal (e.g., child or elder abuse, intimate partner violence), or intrapersonal (i.e., self-directed). Agencies such as the World Health Organization routinely call for increased prevention and intervention approaches to reduce violence, regardless of type. Within the criminal justice context, according to Uniform Crime Reporting statistics from 2016, there were an estimated 386.3 violent crimes per 100,000 inhabitants in the United States and 1,071 violent crimes per 100,000 inhabitants in Canada. One challenge regarding such rates is the definition of violent crime. The rate varies considerably based on definition; in Canada, the rate drops by more than half if possession of a weapon and common assault are excluded from the definition of violent crime. Moreover, the incidence decreases with seriousness of the crime (i.e., murders are less frequent than aggravated assaults). Nonetheless, in both countries, the rate of violent crime has been consistently decreasing since 1990 but remains a serious concern. An important consideration is whether there is one model of violence that applies to the myriad types and contexts of violent behavior. Thus, the entry reviews several theoretical

models of violence and aggressions as well as limitations of such models.

Defining Violence

Aggression is generally defined as behavior directed toward other individuals that is carried out with the immediate intent to cause them harm. *Violence* is considered to be a more severe form of aggression in which harm is intentionally inflicted. It is evident from these definitions that all violent behavior can be categorized as aggressive; however, not all aggressive behavior is violent. Violent crime can be acquisitive, such as armed robbery, or interpersonal violence, such as aggravated assault.

Patrick Tolan and Nancy Guerra noted that violence derives from various pathways, with the most common *types* of violence being situational, relationship, predatory, and psychopathological. These types differ in terms of the proportion of the population likely to show each type, the likely causes, the synergy of risk factors, and the likely age of onset. Violence appears to reflect a continuum within a biopsychosocial model of cause; psychopathological is the most biologically determined but also appears to be the least prevalent in offender populations.

Anger Control Model

In the early 1980s, research by Raymond Novaco regarding a stress inoculation–based understanding of anger was enthusiastically adopted within correctional programming approaches. The basic premise, derived from research on road rage, was that elevated arousal labeled as anger resulted in violence toward others. A useful analogy is that of shaking a soda pop bottle; once the pressure reaches a certain threshold, there is an explosion. Embedded within this model was an effort for offenders to identify physical signs of increased arousal and to utilize relaxation training to mitigate the frequency and severity of responses to situations that elicit an anger response. By the mid-1990s, this model lost favor given that anger did not differentiate violent from nonviolent offenders, and anger scores did not predict reoffending. Nonetheless, anger control is part of a broader, multifactorial program model that focuses on cognition as well as emotion and arousal.

General Aggression Model (GAM)

Notwithstanding a possible biological basis for some criminal violence in some individuals, the preferred explanatory model, the GAM, as documented by Anderson and Bushman, in 2002, considers cognition as the central component for understanding aggression and violence. This integrative theory incorporates the frustration-aggression hypothesis, excitation transfer, and a social-learning perspective such that a violent incident is viewed within the context of a series of social encounters. The GAM underscores key inputs (factors salient in setting up violence), routes (factors that mediate the key inputs of the person and situation), and outcomes (appraisals and decision processes) that lead to actions, which then cycle into the next episode.

Person inputs include key cognitive components such as beliefs, attitudes, and behavioral scripts, which likely filter an individual's predisposition toward a specific situation or appraisals of that situation. For instance, a person who is easily angered (high levels of arousal) and who views the world as a hostile environment where only the strong survive (beliefs) might view someone who insults them warranting violence to teach them a lesson.

Situation inputs include aggressive cues, perceived provocation, frustration, and perceived threats. Behavioral outcomes are deemed to be influenced by cognition, affect, and arousal. Cognitive states include hostile thoughts (e.g., the other person is acting with malice) and behavioral scripts (e.g., only the strong survive). Affective states reflect mood and emotion (e.g., anger), which are often influenced by arousal level (e.g., a high level of arousal often leads to an emotion being labeled *anger*; at lower levels of arousal, the emotion could reflect frustration or disappointment).

Cognition, affect, and arousal are interconnected and can function synergistically, thereby increasing the likelihood of a violent behavioral response in a given situation. Cognition also influences the appraisal and decision process, whereby perceived provocation and general views regarding the utility of violence can lead to a failure to consider multiple responses or the long-term consequences of responses. In short, cognition can lead to a more impulsive behavioral response, consistent with literature describing offenders to

have higher levels of impulsivity when measured using self-report questionnaires or cognitive tasks. The involvement of cognition as both a primer and appraisal mechanism potentially introduces some level of confusion. For example, scripts are listed as both a person factor and a cognitive state activated by a situation.

The GAM dovetails nicely with other correctional programming that considers criminal attitudes (i.e., cognitions) as a primary criminogenic need and important intervention target. It also incorporates an appraisal and decision process consistent with an emphasis on problem-solving as being important in managing violent behavior. Finally, the inclusion of impulsivity highlights the importance of self-regulation within a model for understanding violent criminal behavior, something that is also emphasized in correctional intervention.

Social-Information Processing Model

Within correctional treatment, the preferred conceptual model is a social-information processing conceptualization of violence (sometimes described as *multifactorial*), which had its genesis in the adolescent literature. While it is generally reflected in the GAM, it is a distinct adaptation whereby affect (or the labeling of affect) receives slightly less emphasis and cognitions receive greater emphasis. Indeed, hostile attributions or cognitions, referred to as *schema*, are considered somewhat automatic elements by which they represent a filter through which the individual views the world around him or her. In this manner, it is person centric, asserting that the person and the person's interpretation of events around him or her relate to criminal violence. This model by Ralph C. Serin and Marie Kuriychuk is presented in Figure 1.

Hostile attribution bias refers to the preferred tendency of an individual to interpret a frustrating event involving ambiguous intent as malicious rather than accidental. For instance, such an individual would consider having a drink spilled on him or her in a bar as a deliberate provocation rather than an accident and respond preemptively by assaulting the other person. This reflects attentional cueing (i.e., being vigilant about potential slights) and impulsivity (i.e., failure to consider the consequences of one's actions) rather than an anger problem per se.

Consistent with this model is work by Devon Polaschek and colleagues that has identified specific themes inherent in violent offender thinking by reviewing transcripts of interviews with incarcerated violent offenders in New Zealand. Some might view these themes as cognitive distortions that may be expected to initiate and maintain violent behavior, similar to rationalizations presented in other offender subgroups (i.e., intimate partner violent offenders, sex offenders).

Each theme is presented with an sample statement:

1. Normalization of violence—"I told him this would happen if he didn't pay up in time."
2. I am the law—"People come to me with their problems because they know they can rely on me to sort them out."
3. Beat or be beaten—"I was about 20 when I started to go hard. I learned in jail that if I don't do violence then this [derogatory person term] is going to walk all over me. I don't like hurting people, but what choice have I got?"
4. I get out of control—"I only meant to hurt him a bit. But once I started . . . my friends had to pull me off him. That's how it is sometimes with me."

These examples describe schema that increase the likelihood of violence—specifically, the acceptance and normalization of using violence to maintain or achieve status (*beat or be beaten*), the belief in an entitlement to harm others (*I am the law*), and the schema related to poor self-control. These findings support previous attempts to isolate specific schema or attitudes toward violence and how they contribute to violent behavioral outcomes.

As is apparent, the social-information processing model presented in Figure 1 captures these themes and underscores key intervention targets for violent prevention programming. Implied by this model is that, for offenders with deficits in multiple areas (e.g., attentional cueing, cognitive schema, arousal, and impulsivity), higher program dosage will be required to reduce the likelihood of further violence.

The social-information processing model is more specific for instrumental (i.e., goal directed)

Figure 1 Multifactorial model of violence

Source: Serin and Kuriychuk (1994).

than reactive (i.e., anger based) violence, but both are explained by the model. For example, reactive aggressors, relative to instrumental aggressors, are more likely to infer a hostile intention to another individual in a situation of ambiguous provocation. Furthermore, they are more likely to miss key social cues that would help them interpret the situation. It is the combination of missed social cues and hostile attributions that contributes to a violent outcome. Conversely, attributions for instrumental aggressors are centered on beliefs that using violence will assist with achieving personal goals. A belief that using violence as a means to encourage another individual to pay off a drug debt is an example of a normalized cognitive schema in support of instrumental violence.

Intervention Targets

Most contemporary multifactorial programs for violent offenders target the key constructs reflected in the various models: cognitive schema and attributions, arousal and anger, and impulsivity and self-regulation. Strategies such as behavioral analysis or offense chains also describe high-risk situations and interpersonal interactions that increase violence potential.

Limitations

Of some concern is whether criminal violence necessarily reflects social encounters as presented in the GAM. Armed robbery does not seem to

readily conform to a social encounter. It may be that certain types of criminal violence short-circuit components in these models. Another intriguing observation is that components in contemporary theoretical models of violence are not reflected in current violence risk assessment actuarial scales. Actuarial tools comprise risk factors that have demonstrated statistical or empirical associations with an outcome of interest (i.e., violent offending) and may include items not captured in theoretical models of violence. More common is that some aspects of these constructs are incorporated as risk factors in structured professional judgment assessments for violent offenders. Structured professional judgment tools include actuarial and empirically derived risk factors, in addition to considering contextual or individual factors that may further impact ones' level of risk. It is an empirical issue whether inclusion of these theoretical constructs demonstrably increases predictive accuracy for future violence within offender populations or for subtypes of violent offenders.

Final Thoughts

Existing theoretical models of violence highlight the importance of cognitions in contributing to the frequency and expression of violent crime. Both external events and internal states are mediated by cognition in a manner that influences the likelihood of violence.

As such, cognitions in support of violence remain a primary consideration in violent offender treatment. These models, however, are less specific regarding issues such as intent, motivation, and severity, which are important in interventions and for understanding violent offender heterogeneity.

THERAPEUTIC COMMUNITIES

Therapeutic communities utilize the social environment (sometimes referred to as the *therapeutic milieu*) as the basis for personal change. Derived from a group-based approach to treatment aimed at rehabilitating traumatized service men, therapeutic communities emerged in Europe after World War II. Within Western Europe and particularly the United Kingdom, therapeutic communities have been active in rehabilitating people who have committed offences for over half a century.

Therapeutic communities provide group therapy within a social environment, which emphasizes a distinctive set of values, clinical practices, and organizational relationships. Resident involvement, shared decision-making, and member accountability to peers are central to understanding the work of therapeutic communities. The defining aspect of these services is the nature of the social relationships within the institution, which enable participation; personal empowerment; and collaborative, group-based interaction.

Therapeutic communities have maintained a leading role in the rehabilitation of people who have offended when interest in providing treatment services waned during an era of rehabilitative pessimism. Although some important differences can be observed, they have also provided a sustained and influential intervention in North America for the treatment of those with addictive (i.e., substance abuse) disorders. These differences as well as the similarities will be explored further in this entry. This entry also discusses the influences on the development of therapeutic communities, considers differences between

democratic and hierarchical therapeutic communities, explores theories and treatment models, considers the role of the therapeutic within mental health and forensic services, and reviews research, outcomes, and impact.

Influences on the Development of Therapeutic Communities

Therapeutic communities adopt the view that the social systems and relationships within the treatment setting have a profound impact on those residing within them. In part, therapeutic communities have origins in the Quaker movement, which advocated the importance of treating patients as capable, trustworthy, and having the capacity to take responsibility. They also acknowledge the potential harm done to people by institutions that stigmatize, erode personal identity, and disempower.

A number of other influences can also be identified. The social upheaval following the end of World War II, where traditional structures and arrangements were challenged, created the conditions for social change more generally. An interest emerged in social factors, group relations, and education. Secondly, developments in social psychiatry in the 1960s emphasized the importance of social relationships in mental health and well-being. This acknowledged that the social arrangements in an organization can be used as either a healthy, therapeutic force or a force complicit in the maintenance of psychological ill-health. When the institution empowered patients in their own recovery, treatment outcomes were improved. Social psychiatry also recognized that the way people lived within institutions, the relationships they engaged in, how the system was organized, and how those in charge understood their own authority were more important than the medical treatment offered.

A third influence was the liberalization of institutions in the 1950s and 1960s. The work of the sociologist Erving Goffman galvanized the momentum to create new social structures with institutions. Goffman recognized how patients' identities became submerged to the requirement of the institution and how social arrangements became a basis for control. The fourth influence was the anti-psychiatry movement associated with

the work of Ronald Lang. This emphasized the harmful effect of institutions and medicalization in promoting unhealthy identities and power imbalances. These reinforced a patient's self-narrative as being ill, largely ignored the role of social structures in psychological disturbance, and promoted the belief that patients were dependent on the skills of others if they were to recover.

Democratic and Hierarchical Distinction

A further development was the simultaneous growth of the therapeutic community movement in North America. Although European therapeutic communities originated in social psychiatry, those in North America predominantly originated from a self-help movement for recovering alcoholics. Advocating culturally popular ideas such as abstinence, personal responsibility, autonomy, communal living, and a skepticism of traditional authority, these therapeutic communities emerged in the 1960s and made a significant contribution to the treatment of addictions. These were referred to as *hierarchical* or *concept therapeutic communities* and have certain differences, as well as significant similarities, with the European communities referred to as *democratic*.

Hierarchical therapeutic communities viewed drug use as a deviant behavior, symptomatic of problems in underlying personality development. Addictive behavior is regarded as a disorder of the whole person, being a symptom rather than main focus of a person's difficulties. The main goal is to help residents achieve a responsible lifestyle free from drug use and emphasize the importance of abstinence. The hierarchical nature of these communities comes from the practice of residents gradually being able to earn greater privileges, responsibility, and influence as they progress through treatment. Democratic therapeutic communities, on the other hand, place greater emphasis on group and community psychotherapy and the interpersonal and social learning that occurs when part of a group.

Although predominantly found in North America, hierarchical therapeutic communities are also present in Europe and share many core features with the democratic communities. Both emphasize democratic processes, where residents are responsible for community decision-making, and both prioritize the

role of residents in the running and organizing of community life. Hierarchical therapeutic communities increasingly accept the need for some professional expertise, and both view the change process as being derived from the interpersonal learning that occurs through community living.

Theory and Treatment Model

Therapeutic communities evolved more from a set of values rather than a particular psychological theory. These values reflect the importance of respect, belonging, and empowerment. Psychological change mechanisms are intertwined within a social therapy process, which has its basis in this underlying value system. These can be understood from different theoretical perspectives. Central to the change process is the learning that takes place from interpersonal relationships and interactions within the therapeutic community. This includes skills in problem-solving and conflict resolution, the development of insight, the revision of unhelpful belief systems about self and others, and the learning derived from interpersonal feedback. The term *living learning* has been coined to describe the nature of the therapeutic work that takes place in the therapeutic community. This recognizes how any institution can, when certain conditions are in place, provide a range of opportunities for interpersonal and social learning; attitudes and beliefs can be explored while allowing residents to develop new interpersonal, social, and life skills.

Psychoanalytic ideas emphasizing the role of the unconscious have also been used to understand and examine group and collective processes. Psychoanalysis emphasizes the importance of insight into finding resolution to psychological distress and conflicting drives and needs. The use of psychoanalysis in therapeutic communities tends not to be practiced the way it would traditionally be in the consulting room but rather in terms of understanding social processes. These processes include how groups and individuals relate to each other, how staff-team dynamics emerge, and the way relationships within the institution are developed. An important role for clinicians within a therapeutic community is to create and sustain the culture of communication between community members and ensure that, within the organization, as much responsibility as is

reasonable is invested in its members. A strong therapeutic culture of enquiry, where residents hold each other accountable, has led some commentators to consider the therapeutic process more as social analysis, where the community examines behaviors with an intense rigor. Organizational theory, which examines the relationship between structure, interpersonal processes, and individual behavior, has also been useful in understanding dynamics within teams and the organization.

Therapeutic Processes

Although some differences are observed, there are a number of common activities found in therapeutic communities. The most important and defining aspect of their clinical practice is the therapeutic milieu; however, all therapeutic communities recognize the importance of therapeutic groups. These can either be small group sessions or large meetings involving all members of the community, staff, and residents alike. The themes explored in small group sessions are shared with all members of the community in line with a culture of openness, transparency, and nonconfidentiality.

Community meetings are chaired by an elected resident chairperson, and an agenda is followed. Typically, this agenda includes decision-making over who should take responsibility for which tasks, an exploration of any interpersonal problems experienced between members, and providing support for those experiencing distress. Residents are responsible for choices and the decision-making necessary for community living.

Many therapeutic communities also include additional creative therapies such as psychodrama and art therapy. Some therapeutic communities offer individual sessions; however, this tends not to be common practice but can occur in those communities that are adapted for people with complex needs, such as those with a mental illness.

Disorders Treated

Therapeutic communities are found within community, health, and criminal justice settings. Patients originally treated in therapeutic communities presented with symptoms of mental illness following their experiences in combat. Although some

therapeutic communities adapted for people with psychosis still remain, therapeutic communities are primarily designed for those experiencing personality or addictive disorders. Therapeutic communities consider mental disorder and interpersonal and relationship difficulties as being interlinked, and many individuals referred are assessed as having personality disturbance or a diagnosable disorder. They generally adopt a biopsychosocial perspective to understanding psychological disorder. In addition to dispositional factors, this emphasizes the importance of social and interpersonal functioning in the development and maintenance of an individual's problems. This is particularly the case in therapeutic communities designed for those who have committed criminal offenses where treatment focuses primarily on the relational, social, and affective problems associated with offending. Therapeutic communities are also found in mental health settings and within the community where they provide treatment for those with personality disorders and other mental health, emotional, and social problems.

Research and Outcomes

An evidence base supporting the effectiveness of therapeutic communities has been slow to emerge. Although some early practitioners evaluated their work, questions remained about whether this provided conclusive evidence of their effectiveness. Some of these criticisms stem from the lack of a randomized control trial, recognized as the *gold standard* in demonstrating efficacy. Furthermore, some of the research quality has been variable, and some reviewers have argued that methodological flaws and design weaknesses have limited the extent to which conclusions can be reached about their effectiveness.

Despite these problems in research quality and scope, evidence since the late 1990s provides greater support for the utility and effectiveness of therapeutic communities in the treatment of those who have committed offences. Improvements in mental health, emotional well-being, and reduced rates of self-harm and attempted suicide are consistently found. There is also reliable evidence that treatment in a therapeutic community is effective in improving behavior within the treatment setting, for example, by reducing violent behavior and illicit drug use, changing antisocial attitudes

and belief systems, and improving interpersonal relating. Therapeutic communities are regarded as a particularly effective intervention for offenders with a personality disorder, and research with this population has demonstrated improvements in mental health, interpersonal relating, and social integration. Social climate and quality of life research has also provided overwhelming support of how therapeutic communities provide a safe, decent, and humane treatment environment.

Evidence from the hierarchical, addiction-based therapeutic communities strongly points to their effectiveness in reducing rates of reconviction. Although research focusing on democratic therapeutic communities is more limited, there is sufficient evidence to suggest that they are effective in reducing rates of reconviction for certain types of offender, particularly those with personality disorders and those who have committed repeat sexual and violent offences. One overwhelming conclusion from the research is the importance of time in treatment on outcome. The majority of changes reported occurred only for those who had been in treatment for at least 18 months, indicating that gains are contingent upon residents engaging in treatment for substantial periods of time.

Wider Impact

Therapeutic communities have significantly influenced developments in offender rehabilitation and services for those with a personality disorder. They have also provided a model for humane containment that emphasizes the potential of relationships and organizational practices to create the conditions for personal change. These features of forensic services have become central in service provision within the UK prison and personality disorder services, and hierarchical therapeutic communities continue to provide a major role in addiction services in North America.

THERAPEUTIC JURISPRUDENCE AND PROBLEM-SOLVING COURTS

Since the early 1990s, scholars have begun to consider mental disability law issues through the filter of therapeutic jurisprudence, a model by which to assess the impact of case law and legislation affecting persons with mental disabilities. Therapeutic jurisprudence studies the role of the law as a therapeutic agent, recognizing that judicial decisions and statutes, courtroom procedures, and lawyers' roles may have either therapeutic or antitherapeutic consequences and questions whether such rules, procedures, and roles can or should be reshaped so as to enhance their therapeutic potential, while not subordinating due process principles. Problem-solving courts, such as mental health courts, are important exemplars of the practical utility of therapeutic jurisprudence. Such courts are grounded and rooted in therapeutic jurisprudence, and they reflect therapeutic jurisprudence theory in practice. This entry examines the aims and principles of therapeutic jurisprudence and discusses its implications with regard to problem-solving courts, with an emphasis on mental health courts.

Aims and Principles of Therapeutic Jurisprudence

Therapeutic jurisprudence focuses on the law's influence on emotional life and psychological well-being, with its ultimate aim being to determine whether these rules, procedures, and roles

can or should be altered so as to enhance their therapeutic potential *while not subordinating due process principles*. There is an inherent tension in this inquiry, but David Wexler—one of the pioneers of this school of thought—identifies how it must be resolved: The law's use of "mental health information to improve therapeutic functioning [cannot] impinge upon justice concerns" (1993, p. 21). Thus, an inquiry into therapeutic outcomes does not mean that therapeutic concerns trump civil rights and civil liberties.

In recent years, scholars have considered a vast range of other topics beyond mental disability law through a therapeutic jurisprudence lens, including but not limited to domestic relations law, criminal law and procedure, employment law, gay rights law, and tort law. Therapeutic jurisprudence enables scholars and practitioners to utilize socio-psychological insights into the law and its applications; furthermore, it is part of a growing comprehensive movement in the law toward establishing more humane and psychologically optimal ways of handling legal issues collaboratively, creatively, holistically, and respectfully. It optimizes psychological well-being of individuals, relationships, and communities dealing with legal matters, by acknowledging concerns beyond strict legal rights, duties, and obligations. In seeking to use the law to empower individuals, enhance their rights, and promote their well-being, therapeutic jurisprudence has been described as a sea change in ethical thinking about the role of law. Moreover, it is part of a movement toward a more distinctly relational approach to the practice of law, one that emphasizes psychological wellness over what has been called *adversarial triumphalism*. Therapeutic jurisprudence thus supports an ethic of care.

A central principle of therapeutic jurisprudence is a commitment to dignity. Professor Amy Ronner has described therapeutic jurisprudence as conferring *three Vs*—voice, validation, and voluntariness. Ronner argues

What "the three Vs" commend is pretty basic: litigants must have a sense of voice or a chance to tell their story to a decision maker. If that litigant feels that the tribunal has genuinely listened to, heard, and taken seriously the litigant's story, the litigant feels a sense of validation. When

litigants emerge from a legal proceeding with a sense of voice and validation, they are more at peace with the outcome. Voice and validation create a sense of voluntary participation, one in which the litigant experiences the proceeding as less coercive. Specifically, the feeling on the part of litigants that they voluntarily partook in the very process that engendered the end result or the very judicial pronouncement that affects their own lives can initiate healing and bring about improved behavior in the future. In general, human beings prosper when they feel that they are making, or at least participating in, their own decisions. (2002, pp. 94–95)

When procedures give people an opportunity to exercise voice, their words are respected, their views are taken into account, and there is less coercion in the process. The question that is asked in each instance is whether any aspect of the legal process—a court decision, a statute, a regulation, and a lawyering practice—adheres to the *three Vs* as described by Ronner.

Mental Health Courts

In the context of mental disability law, scholars have considered the therapeutic jurisprudential implications inherent in such issues as civil commitment, institutionalization, the forensic mental health process, international human rights law, tort liability, sexual offender law, the death penalty, and many more. One of the most important considerations is the relationship between therapeutic jurisprudence and problem-solving courts, such as mental health courts (other problem-solving courts include drug courts, veterans courts, domestic violence courts, teen courts, and homelessness courts).

Such courts follow the legal theory of therapeutic jurisprudence, so as to best improve justice by considering the therapeutic and antitherapeutic consequences that flow from substantive rules, legal procedures, or the behavior of legal actors. They are designed to deal holistically with people arrested when mental illness rather than criminality appears to be the precipitating reason for the behavior in question. The mental health court judge seeks to divert the individual from the standard criminal court in exchange for an agreement

to participate in community treatment and to help participants avoid future criminal involvement.

Mental health courts are premised on team approaches; the judge is assisted by representatives from justice and treatment agencies to screen offenders to (a) determine whether there would be a risk of violence if they were to be released to the community, (b) devise appropriate treatment plans, and (c) supervise and monitor the performance in treatment. The judge is part of a team that decides whether the individual has treatment needs and can be safely released to the community. The team formulates a treatment plan; next, a case manager and monitor (employed by the court) track the individual's participation in the treatment program and subsequently submit periodic reports to the court concerning the individual's progress. Participants report to the court on a periodic basis so that treatment compliance can be monitored by the judge; additional status review hearings are held when needed.

To be effective, the judge needs to develop enhanced interpersonal skills and awareness of a variety of therapeutic techniques. These skills and techniques help the judge motivate the offender to participate effectively in treatment. The judge must be able to both build trust and manage risk, convey empathy and respect, communicate effectively with the individual, and listen carefully to what the individual has to say. Optimally, this aims to fulfill the individual's need for voice and validation and earns the individual's trust and confidence. The employment of motivational interviewing technique is a significant part of this process.

These courts provide nuanced approaches and may, eventually, signal a fundamental shift in the criminal justice system, one often premised on retribution and punishment. A successful mental health court needs (a) a therapeutic environment and dedicated team, (b) an environment free from stigmatizing labels, (c) opportunities for deferred sentences and diversion away from the criminal system, (d) the least restrictive alternatives, (e) decision-making that is interdependent, (f) coordinated treatment, and (g) a review process that is meaningful. It is essential that such courts be free of any pretextual dishonesty, which refers to either implicitly or explicitly accepting testimonial dishonesty or engaging in dishonest

(and frequently meretricious) decision-making, specifically when witnesses (e.g., expert witnesses) show a propensity to purposely distort their testimony in order to achieve desired ends.

Skeptics argue that these courts are too dependent on the aura of the charismatic judge. However, research demonstrates that litigants before a judge who adheres to these principles report a higher score on a dignity scale (and a lower score on a perceived coercion scale) than any previously studied group of criminal defendants. The real-life experiences of the litigants in cases before this judge demonstrate that such a court can be a noncoercive, dignified experience that provides therapeutic jurisprudence to those before it.

There are two concerns about mental health courts that have not been the focus of much attention: the lack of concern paid to the question of *competency* in the mental health court process and the lack of concern paid to the question of the quality of *counsel* made available to individuals in the mental health court process. Given the impaired cognition that accompanies many mental disorders, there is little evidence to suggest that mental health courts ensure that prospective candidates are competent to accept the plea bargains into which many enter, as required by constitutional law. Indeed, the *target litigant* of mental health courts may be precisely the sort of individual who does not fully comprehend the purpose, requirements, and roles in the courts. In fact, research has revealed that the majority of defendants at two mental courts lacked *nuanced information* about the trial process and that a minority of defendants had *impairments in legal competence*. Thus, a thorough evaluation of the offender's mental competence is essential in the mental health court process. One intriguing recommendation has been to create *competency courts* as subspecialty courts within mental health courts to improve the competency process and reduce the unnecessary time that persons with mental illness spend in jail; however, there it does not appear that this recommendation is being acted upon.

On the question of counsel, there are serious concerns as to whether persons with mental disabilities receive adequate legal representation in civil commitment and criminal justice processes.

Some clients with mental illness may lack confidence that their attorney is acting in accordance with their wishes, especially if the attorney has no specific training in mental disability law. Thus, to ensure that defendants receive dignity and respect, are given a sense of voice and validation, and are treated with fairness and good faith, it is important that they be aware of the advantages and disadvantages of accepting diversion to mental health court.

THREAT/CONTROL-OVERRIDE MODEL

The threat/control-override (TCO) model provides scholars with a means for understanding the link between psychotic disorders and violent behavior. While trying to understand the association between mental illness and violence, Bruce Link and his colleagues identified a subset of psychotic symptoms that the researchers term *TCO symptoms*. Individuals who are experiencing TCO symptoms are likely to act out violently in two situations: if the symptoms cause the person to feel threatened by others (i.e., threat) or if the symptoms override internal controls that might otherwise block violent tendencies (i.e., control-override). In the first instance, if an individual defines the situation as threatening and real, violence is likely to occur in a rational fashion. In the second instance, if a symptom leads to a definition of a situation that overwhelms the individual, behavioral constraints are likely to fail. In sum, violence is likely to occur when an individual suspends concerns about the irrationality of psychotic symptoms and defines the situation as real, thus responding in a rational way to the perceived threat or behavioral controls is overridden. This entry reviews the theoretical foundations, empirical developments and current status, and future directions of the TCO model.

Theoretical Overview

Link and his colleagues incorporated a symbolic interactionist perspective in their work. The symbolic interactionist perspective is a major theoretical framework in sociology. This perspective hones in on the idea that an individual's behavior is influenced by social interactions. Within these

social interactions, individuals attach meanings to objects, events, and behaviors, which are derived from social interaction and modified through individual, subjective interpretation. Thus, these interpretations, which are socially constructed, lead to definitions of situations. Definitions of situations influence how an individual will behave.

While constructing the theoretical framework of TCO symptoms, Link and his colleagues drew from the Thomas theorem that has been closely associated with the symbolic interactionist approach. The Thomas theorem states that, "if people define situations as real, they are real in their consequences." In other words, if an individual's perception of a situation is defined as real to him or her, then the repercussions of those definitions will result. This association between the Thomas theorem and the symbolic interactionist perspective exists since the theorem highlights the importance of an individual's interpretations of situations and how these interpretations influence the individual's own behavior.

Definitions of situations are important and have been a central theme in sociological and criminological theories and have been linked to violent behavior. Definitions of a situation are consequential because they dictate the motivation to act. It is important to understand an individual's definition of a situation in order to comprehend their behavior. Thus, Link and colleagues drew on the interactionist principle, emphasizing that definitions, even if they result because of psychotic symptoms, may influence violent behavior. Stated another way, if an individual is no longer concerned that he or she may be experiencing psychotic symptoms and accepts that what the individual is experiencing is subjectively real to that individual, violence is likely to unfold in a rational fashion.

As stated previously, Link and colleagues predicted that TCO symptoms are likely to lead to violence in two situations: if the symptoms cause the person to feel threatened by others (i.e. threat) or if the symptoms override internal controls that might otherwise block violent tendencies (i.e., control-override). For instance, if an individual defines a situation to be dangerous or threatening (i.e., a threat delusion), then a violent response is viewed as justifiable and rational in that situation, regardless if the situation is a delusion or real.

What matters, according to the symbolic interactionist perspective and Thomas theorem, is that the individual believes the situation to be real. A few examples of an individual who may be experiencing threat delusions include if that individual believes he or she was being secretly tested or experimented on, believes that someone was plotting against or trying to hurt or poison him or her, or believes that people were spying on the individual.

Conversely, control-override symptoms occur if the definitions of a situation lead the individual to overwhelm the individual's usual behavioral constraints that repress violent outbreaks. For instance, Link and colleagues provide the example that an individual may believe that God is commanding the individual to kill someone and, in that instance, that person's definition of the situation would include a divine instruction to act out violently. This definition of the situation, therefore, would influence violent behavior due to the idea that God wanted the individual to act violently. Thus, delusions involving mind or body control are part of the control-override subset of delusions. A few examples of these delusions include the belief that someone was reading the individual's mind, the belief that others could hear the individual's thoughts, or the belief that the individual was under the control of some person, power, or force.

Empirical Developments

To test their theory, Link and his colleagues examined data from a nationally representative, epidemiological study of Israeli citizens. The study participants were first screened for potential mental illness, then they were asked questions about whether or not they had recently experienced certain psychotic symptoms and had engaged in a host of behaviors, including violence. As expected, the researchers found that mentally disordered participants who reported experiencing TCO symptoms were more likely to report engaging in violent behavior than disordered and nondisordered participants who did not report experiencing those symptoms. In further analyses of these data, the researchers even found that those TCO symptoms completely explained the increased prevalence of violence among participants with

mental disorders. In other words, in the absence of TCO symptoms, the mentally disordered participants in the Israeli study were no more likely to have been violent than the participants who had no mental illness at all. These findings provided strong initial support for the TCO–violence connection, and other researchers soon attempted to replicate these findings using other study populations.

Replications of the early TCO research provided mixed results. Using data from an epidemiological study of American citizens from several U.S. cities, Jeffrey Swanson and his colleagues also found that participants who had reported experiencing TCO delusions were more likely to have reported engaging in violent behavior. These findings provided additional support for the TCO model because they confirmed the prior results using a completely different study population. That said, their results were different in one major way. While the presence of TCO delusions explained all the difference in violence between disordered and nondisordered participants in the Israeli study, TCO symptoms did not explain the difference in violence in the American study. TCO symptoms explained violence among disordered participants with psychotic symptoms; however, they could not explain the increased prevalence of violence among the disordered sample as a whole. Rather, mentally disordered participants were more likely to have engaged in violent behavior, whether or not they also experienced TCO delusions. This finding called into question whether the TCO model could adequately explain why individuals with severe mental illness bore an increased risk of violent behavior.

Up to this point, empirical tests of the TCO model had used cross-sectional data that asked participants to report symptoms and behaviors that they had experienced over a particular time period prior to the study interview. While informative, this type of study design limited the information researchers could obtain. For example, cross-sectional data could not explain how symptoms changed over time, how their relationship to violence changed over time, or differentiate whether the symptoms came before violence (or vice versa). In contrast, longitudinal data could allow researchers to examine the impact of symptoms at a particular time point (Time 1) on

behavior reported at the following time point (Time 2) because the participants would be asked the same questions at regular intervals several times over a study period. To fill this gap, a group of researchers led by Paul Appelbaum analyzed data from a year-long longitudinal study of recently discharged psychiatric patients.

The researchers examined the effect of interviewer-rated TCO delusions at a particular follow-up interview on violence perpetration during the next follow-up period. The researchers found that, contrary to prior studies reporting a positive relationship between TCO symptoms and violence (i.e., as TCO symptoms increase, violence increases), the presence of TCO delusions at a particular follow-up period actually *reduced* the likelihood of violence perpetration over the next follow-up period (i.e., a negative relationship). This presented a major challenge to the notion that TCO delusions could explain why individuals with severe mental illness appeared to be more violent than nondisordered individuals. In fact, these findings suggested that experiencing TCO delusions might actually reduce the likelihood of violence.

In a subsequent analysis of the data, Appelbaum and his colleagues reexamined the TCO data using self-report, rather than ratings from the clinical interviewers, and assessed the relationship between TCO delusions and violence retrospectively. In other words, they examined whether patients who reported experiencing TCO delusions also reported engaging in violent behavior over the last follow-up period (similar to the methods used in previous studies). Consistent with the prior research, these results showed strong, positive associations between self-reported TCO symptoms and violence perpetration.

Current Empirical Status

The major differences in empirical findings highlighted in these early, landmark studies have persisted. While there is still some speculation regarding the nature of the relationship between TCO delusions and violence, much of the inconsistency found across studies appears to be methodological. For instance, studies that employ retrospective designs (like those early epidemiological studies) tend to find relationships between the symptoms and violence, while studies

prospectively examining longitudinal data find no relationship or even find that violence decreases after experiencing TCO symptoms. In addition, a strong relationship between TCO delusions is commonly found in studies that rely on symptom self-reports or researcher discretion when examining case files. Conversely, studies utilizing clinician- or interviewer-rated symptomatology tend to report weaker relationships (if any at all).

Methodological issues aside, TCO–violence research has revealed a number of interesting findings. For example, TCO delusions may be more associated with violence among men than women. Moreover, violence associated with TCO delusions may be more likely in the context of certain types of hallucinations, substance abuse, or when patients are noncompliant with treatment (i.e., when patients experiencing those delusions do not take their medications). Also, individuals with high levels of certain underlying personality traits, such as impulsivity, may react to TCO symptoms more violently. Finally, whether TCO delusions lead to violence may be related to the degree of emotional distress that those delusions cause. Individuals who experience greater distress because of their TCO symptoms may be more likely to be violent out of anger, fear, or anxiety.

Future Directions

Based on the model's original idea—*real in its consequences*—the impact of TCO delusions on violence may be conditional. That is, a one-size-fits-all approach to TCO delusions may be unwarranted. Brent Teasdale and colleagues' work, for example, suggests that the impact of threat delusions on violence is conditional on gender. Men respond to these delusions with a fight-or-flight response, but women respond with a tend-and-befriend coping response. Future research may consider other ways in which the impact of TCO delusions on violence may vary, such as by insight. If an individual recognizes the delusion as such, the individual may not perceive it to be real and therefore not experience violent consequences.

THREATS IN PRISONS

In prison environments, people are at a high risk of being victimized—for example, through verbal intimidation, theft, or exploitation. Tactics used when disputes such as threats or accusations arise are often reciprocal, tending to escalate conflicts into violence. This entry explores the prevalence of violence in prisons, factors that contribute to the escalation of conflicts into violence, and prevention efforts toward reducing threats to prisoners’ safety.

Prevalence of Violence and Victimization in Prison

Research in England into the background circumstances of assaults in prisons is provided here as empirical evidence regarding the levels of victimization among prisoners. In 2015, in England and Wales, in a national prisoner population of over 86,000, there were over 20,000 assaults by prisoners on other prisoners, one in 10 of which were serious assaults. These are the official figures—those incidents that have come to the attention of staff and for which a prisoner was charged with an offense and found guilty. The underlying rate (of hidden assaults) is likely to be much higher.

The rate of assault in custody can also be measured via a self-report survey. Every prison in England and Wales is subject to inspection by HM Prisons Inspectorate. Each inspection includes a survey of prisoners, and the data are aggregated for annual reports. In 2015–2016, the Chief Inspector of Prisons reported that 9% of prisoners self-reported having been “hit, kicked or assaulted” by another prisoner during their time in that prison. The inspectorate’s survey reveals the extent of other forms of victimization, including threats, theft, and insults. Taking all harmful behavior into account, 30% of prisoners reported having been victimized by another prisoner.

Victimization, Conflict, and Violent Incidents

Research conducted by Kimmet Edgar, Ian O’Donnell, and Carol Martin on fights and assaults in prisons in England and Wales analyzed 141 violent incidents as the culmination of conflicts between prisoners. Conflicts are situations in which competing interests are pursued by those involved in uncompromising ways. To see a fight or assault as the outcome of conflict encompasses the interests that were in dispute between the parties, their relationships, the tactics each person used, and the social environment in which the conflict developed.

How people handle disputes can aggravate the situation and make it more likely that physical force will be used. Common tactics in prison conflicts included threats, insults, other verbal abuse (including racist language), and physical intimidation. The tactics that led to fights and assaults often included one party (or both) victimizing the other.

In the violent incidents analyzed by Edgar and colleagues, at least one party had threatened the other prior to 46% of the fights or assaults. Verbal challenges were used prior to 42% of violent incidents. In about one third of the incidents, there were prior invasions of personal space, insults, or commands. When they appeared in combination, these harmful behaviors were reliable predictors of physical violence. Thus, the high risk of being victimized—for example, through threats, theft, or exploitation—exacerbates conflicts in prison, creating incentives for prisoners to use force.

Values also contribute. A widespread belief that force is a necessary reaction to being victimized leads some prisoners to use force as a way of regulating behavior. Mutual victimization often preceded a fight or assault. Of the prisoners Edgar and colleagues interviewed following a fight or assault, 78% described mutual victimization prior to the use of force, 31% described mutual insults, and 41% described mutual threats. Reciprocal victimization, prior to violent incidents, suggests that there may not be clear distinctions between victim and perpetrator.

When Conflicts Become Power Contests

In the restricted social environment of prison, it can be difficult to use avoidance tactics when faced with a possible aggressor. Power contests arise when two prisoners each sense that the other is trying to dominate him or her. Both respond with aggressive tactics, propelling the dispute to a violent outcome.

Concerns about intimidation are widespread in all types of prisons. Conflicts that begin with a clash over some material object become a test of who will dominate whom. In response, each person insults, threatens, challenges, verbally abuses, or physically intimidates the other. When people fight over a seemingly trivial object, such as a yogurt or access to a pool table, they are likely to be defending their honor and self-respect. As one prisoner explained, tobacco would not be worth fighting over outside prison, but in jail, the theft of even a small amount would pose a risk to her self-respect.

Characteristics of power contests include the following:

- *respect*—being dominated is the central concern
- *narrow focus*—on one other prisoner or opponent
- *sizing up*—gauging the opponent's strength of character
- *win/lose*—compromise is considered a weakness
- *power values*—force determines the outcome
- *precedent*—losing this dispute will fix the individual in an inferior position

Tactics such as challenges, threats, and hostile gestures typically arise in power contests. Those involved try to settle the conflict first through coercion and then through physical violence. Respect is a central motivation, and a boost in self-respect for one is predicated on a loss in self-respect for the other. Mutually acceptable resolutions are ruled out when the desired outcome is defined in this way.

Lifestyle Factors Related to the Risk of Prison Violence

Individual and social characteristics can increase risks to safety. Exploiting other prisoners, getting into debt, and appearing to pass information to staff are lifestyle choices that can increase susceptibility to violence. A prisoner who develops skills of conflict resolution may be less likely in the future to be drawn into using threats when faced with a dispute and therefore less likely to be involved in prison violence. A prisoner who has no previous experience of violence may become involved (as perpetrator, victim, or both) if circumstances change. In particular, using aggressive tactics in encounters with fellow prisoners, such as accusations and ultimatums, is likely to drive disputes toward violence.

In research conducted in Tennessee, Richard McCorkle described situations in which prisoners used force to demonstrate their toughness. These prisoners feared that other inmates would consider them to be weak and vulnerable. Their use of force was intended to deter others by establishing a reputation that would protect them from future victimization.

The social dimension includes peer pressure, incentives in the prison regime, and the level of safety in general in the institution: Prisons that feel less safe provide an incentive to prisoners to

prepare to use force to defend their interests. The ethos of a prison is more or less tolerant of violence (the uniformed staff can view fights as inevitable or consider it their duty to prevent violence; other prisoners justify, condone, ignore, or condemn injurious force).

The following summary of this evidence helps to prepare the ground for a discussion of possible solutions:

- Conflict is endemic in prisons.
- The high risk of being victimized exacerbates prison conflicts.
- Tactics used in prison disputes tend to escalate rather than resolve conflicts.
- Antisocial behavior, such as threats or accusations, was often reciprocal.

Other factors that contribute to violence include the following:

- racial and cultural tensions and misunderstandings
- emotions such as frustration, anger, and shame
- transitory relationships and lack of familiarity with peers
- low self-esteem

Reducing the Risks of Violence in Prisons

The prevention of prison violence is a complex challenge. Analyzing the causes of violence as conflict and applying conflict resolution provide dynamic and effective tools for managing safety in prisons.

The large variety in prison environments and the multiple factors that influence violent outcomes show that each prison needs to gather evidence on the nature of conflict. Prevention strategies must take a broad perspective, incorporating a range of measures, each of which makes a distinct contribution to preventing situations from escalating into violence. Officials can change the social environment to reduce the risk of violence by

- fulfilling prisoners' basic human needs,
- protecting prisoners' personal safety,
- providing opportunities to exercise personal autonomy, and
- building in mechanisms for prisoners to resolve conflicts.

In December 2015, the United Nations General Assembly adopted a revised set of minimum standards for the treatment of prisoners (the Nelson Mandela Rules). Guidance included in the rules suggests effective methods for preventing violence. According to Rule 36 of the Nelson Mandela Rules:

Discipline and order shall be maintained with no more restriction than is necessary to ensure safe custody, the secure operation of the prison and a well-ordered community life.

Some aspects of the prison social environment positively require discipline and conflict resolution to work together. The disciplinary role of staff—challenging verbal abuse and threats, protecting personal property from theft, and confronting prisoners when they harm others—can prevent conflicts from escalating into violence. Early intervention by officers is likely to produce positive outcomes more than staff using force to stop violent incidents after they occur. When officers consistently confront victimization, an important cause of violence is removed, and prisoners gain confidence that problems can be solved without using force. In prisons where verbal abuse, harassment on racist or tribal grounds, theft, or exploitation is widespread, prisoners tend to use force to defend their interests.

Rule 36 also explains that discipline must operate “with no more restriction than is necessary.” Methods intended to improve safety based on incapacitation alone—for example, through high use of segregation, universal lockdowns, or use of force by staff—have been shown to be ineffective and unlikely to deliver a safer environment.

Rule 38 of the Nelson Mandela Rules states:

Prison administrations are encouraged to use, to the extent possible, conflict prevention, mediation or any other alternative dispute resolution mechanism to prevent disciplinary offences or to resolve conflicts.

Prisons that provide nonviolent ways of resolving differences, including wing forums, trained, impartial mediators, or formal opportunities to negotiate, are better equipped to resolve conflicts before they result in a fight or assault. Prison

officials need to create a space in which nonviolent methods are credible, resourced, publicized, and workable.

Because the roots of prison violence are complex, prevention requires diverse measures. Such measures might include the following:

- Mechanisms for resolving conflicts among prisoners are easily accessed by all prisoners.
- All prisoners are protected from victimization.
- Officers are alert to any aggressive behaviors.
- Risk assessments are based on dynamic factors and are regularly updated.
- Dynamic security enables staff to recognize signs of trouble early.
- Regular wing meetings discuss causes of tensions.
- Prisoners' basic human needs are met.
- Racial and/or ethnic tensions are managed.
- Prisoners' skills in responding to conflict are developed.
- Prisoners are consulted about how to reduce violence.
- Mediation is widely available.
- Regular prisoner surveys about victimization reveal factors contributing to violence.
- Rules against drugs, weapons, and other contraband are rigorously enforced.
- *High crime* areas within the prison are better supervised.
- Good relationships are fostered.
- Nonviolent responses to conflict are rewarded.

THREE STRIKES LAWS

Public concern over offenders with prior convictions committing new crimes resulted in the U.S. federal government and 25 states passing reforms during the 1990s that reduced judicial discretion at sentencing and enhanced the sentences of recidivist offenders who committed new crimes. Designed to deter offenders with prior records from committing new crimes and incapacitating them if they did, these reforms became known as *three strikes laws* because, in the parlance of baseball, with a *third strike* (conviction) an offender was *out* (received life imprisonment).

Three strikes laws are based in habitual offender statutes that many states already used to enhance the sentences of recidivists convicted of new crimes. First appearing in New York in the 1700s, habitual offender laws generally mandate significant enhancements—including life in prison without parole—to the sentences of those with prior offenses convicted of new crimes. The laws became so popular that by the 1940s, 49 states and the federal government had habitual offender statutes in place that allowed for sentence enhancements for recidivist offenders convicted of new crimes. This entry reviews the emergence and implementation of three strikes laws and then discusses the criticisms and proposed reforms of these laws.

Getting Tough on Crime

During the 1970s and 1980s, critics from both the political left and the political right attacked

sentencing *and* correctional policies in the United States as being ineffective at addressing offender recidivism. Some critics argued that punishment was the appropriate response to these offenders, fueled in part by the apparent failure of rehabilitation to effectively reduce crime.

The drive to punish recidivist offenders through sentencing enhancements originated in the *nothing works* movement of the 1970s. Critics of rehabilitation pointed to the work of Robert Martinson and his colleagues on the effectiveness of rehabilitation programs to argue that rehabilitation had failed and a new orientation in sentencing that stressed deterrence and incapacitation was needed. This new orientation could be realized through tougher penal sanctions for not only recidivist offenders but also first-time offenders. In their critique of existing policy, reformers argued that to fight crime, the conditions of incarceration had to become more austere and sentencing policy needed to be tailored less to the needs of offenders and more toward protecting society from them. The *nothing works* movement, in particular, targeted the discretion that judges exercised when sentencing offenders. Critics contended that judges enjoyed too much discretion at sentencing and as a result were *coddling* criminals by trying to individualize their sentences to fit offender needs. To address the problem of sentencing discretion, policy would have to change from an orientation that stressed indeterminacy to one emphasizing determinacy and would include presumptive sentences, a narrowing of the range of time to which an offender could be sentenced to serve, and abolition of the opportunity for early release from prison (i.e., parole).

Collectively, these criticisms resulted in a *get tough* movement over the next 40 years that altered both sentencing and penal policy in the United States. Many new prisons were built and the mass incarceration of millions of Americans occurred to the point where, by 2008, one of every 100 adults in the United States was under some form of penal supervision: in jail or prison or on probation or parole. In fact, until recently, public sentiment supported a correctional philosophy that stressed deterrence and incapacitation, especially for offenders with prior records who committed new crimes.

The “Three Strikes and You’re Out” Movement

During the 1990s, public pressure on legislators in both the states and Congress to *do something* about recidivist offenders committing new crimes grew. In response, between 1993 and 1996, a total of 25 states and the federal government passed laws calling for enhanced terms of incarceration for recidivist offenders. In many instances, these enhancements were mandatory; as a result, judicial discretion was either reduced or removed entirely from the sentencing process, and instead, judges use sentencing guidelines to determine appropriate punishment.

Proponents of enhanced sentences for recidivists argued that research provided the justification for treating them as *special cases* worthy of enhanced sentences. These individuals were the *worst of the worst* offenders—they had many prior convictions and had managed to escape punishment due to lax sentencing policies in place at the time. Enhanced sentences for recidivists committing new crimes would serve to deter others from reoffending and incapacitate those who did. High-rate offenders would thus be singled out and receive significant enhancements to their sentences upon being convicted of a new crime. By making these enhancements mandatory and thereby eliminating judicial discretion, these laws aimed to increase the certainty that recidivist offenders actually received the punishment they deserved. Thus, both the severity and the certainty of punishment, two key aspects of deterrence, would be enhanced under these new laws. Proponents thus argued that by enhancing recidivists’ sentences, removing judicial discretion for imposing them, ensuring these offenders served their entire sentence in prison, and excluding them from both parole and *good-time* considerations, crime would finally be reduced.

Implementing Three Strikes Laws

Singling out recidivist offenders for enhancement punishment became a reality in 1993 when Washington became the first state to enact a three strikes law through a statewide initiative that became the *Persistent Offenders Accountability Act* (RCW 9.94A.392). The legislation stipulated

that recidivists who were convicted a third time for certain offenses would receive a mandatory sentence of life in prison without possibility of parole. Furthermore, offenders sentenced under the act would be ineligible for furloughs or good-time reductions to their sentences. The only way an offender could be spared the life-without-parole sentence would be through a pardon granted by the governor. Planners at the time expected that 40–75 offenders would be eligible annually for enhancement to their sentences under the new law.

A year later, California followed suit when Proposition 184 passed and called for even tougher enhanced sentences for recidivists than those that had been adopted in Washington. Proposition 184 actually proposed a two strikes rule: An offender with two prior felony convictions convicted of a third felony would face *double* the sentence he or she would have received without the prior convictions. In addition, Proposition 184 called for offenders who had three prior felony convictions and were convicted of a new felony to receive a mandatory sentence of life in prison. Proposition 184 subsequently became the *model* for three strikes legislation that eventually passed in other states and the federal government.

The Rising Tide of Criticism

Criticism of three strikes initiatives arose almost immediately, particularly with the California model. Assessments of the impact of the three strikes laws appeared in both scholarly and popular press outlets and fostered a lively debate over the direction of sentencing policy both generally and with recidivist offenders specifically. Stories relating to how three strikes laws were being applied appeared in newspapers along with editorials and op-ed pieces—both for and against the laws—over the next several years. Investigative journalists added fuel to the fire when they uncovered instances where it appeared that inappropriate sentences were being given to recidivist offenders under the California law.

Critics of the laws also argued the statutes were unfair because, by reducing or eliminating the discretion of judges and prosecutors, mitigating factors such as an offender's remorse or the potential for an offender's rehabilitation were removed from consideration at sentencing. Other critics pointed

out that due to variation in both the number and type of offenders targeted by these statutes, low-level offenders could face extended terms of incarceration with no hope of parole or even good-time reduction in their sentences. Critics argued that these cases violated the spirit of the statutes; they were designed to target the *worst of the worst* offenders including career robbers or burglars.

Critics also pointed to possible prison overcrowding that could result from widespread use of three strikes laws. Enhanced sentences combined with loss of parole or good-time reductions would create additional strains on an already overburdened correctional system and lead to the diversion of scarce state resources to address those burdens. Finally, some academic researchers published articles in peer-reviewed journals that argued not only did three strikes laws not reduce serious crimes such as murder and robbery, but the empirical evidence showed that states adopting these laws actually experienced increases in serious crime.

Reforming and Repealing Three Strikes Laws

State legislatures have been revisiting three strikes statutes in recent years with an eye toward revising or, in some instances, repealing them. In 2012, for example, Californians passed a statewide initiative, Proposition 36, which was subsequently codified as the *Three Strikes Reform Act*. Proposition 36 eliminated life sentences for nonviolent, less serious crimes perpetrated by recidivists and established a process by which inmates previously sentenced to life in prison under the state's three strikes law could petition the courts to have their sentences reviewed. As a result of this change, some 3,000 offenders sentenced to life in prison under the old sentencing scheme became eligible to have their sentences reviewed. Some observers argued that the change created by Proposition 36 would save California between US\$150 and US\$200 million annually in correctional costs. Successful efforts to reform or repeal three strikes laws have occurred in several states, including Alabama, Colorado, Indiana, Georgia, Mississippi, New Mexico, South Carolina, and Washington.

At the federal level, a Supreme Court ruling in the 2015 case of *Johnson v. United States*

effectively voided the Armed Career Criminal Act, a 1984 law that mandated a term of 15 years to life in prison for firearms possession by people with either three prior convictions for *serious drug offenses* or *violent felonies*. The majority opinion in that case found the component of the law that lengthened sentences as vague, and the discretion accorded prosecutors and judges to determine what counted as a *violent felony* as a violation of the Fifth Amendment to the U.S. Constitution.

Final Thoughts

Three strikes laws illustrate ongoing policy efforts to address crimes perpetrated by previously convicted offenders and are designed to both deter offenders with prior records who contemplate new crimes and incapacitate those who carry out those plans. Three strikes statutes also reduced or eliminated judicial discretion at sentencing by mandating enhanced sentences—including life in prison—for offenders with prior felony convictions who were convicted of a new felony. Three strikes statutes also enjoyed public support as one solution to the problem of stopping recidivist offenders from continuing to engage in criminal behavior.

Three strikes statutes have not been without critics including civil libertarians, criminologists, legal scholars, and policy analysts. Critics have raised issues with the fairness of three strikes enhancements, with the alleged crime-reducing capabilities of the statutes, and with potential Constitutional issues they raise involving the Fifth and Eighth Amendments to the U.S. Constitution. Critics also point to empirical evidence showing that three strikes laws directly contribute to the mass incarceration crisis plaguing the United States and that these laws channel valued state resources from other areas such as health and education to corrections.

With successful efforts in multiple states to either revise or repeal three strikes laws, in 2018 both conservatives and liberals appear to be at the point of agreeing that three strikes laws are an example of a failed criminal justice policy in need of significant revision.

TRANSNATIONAL GANGS

Street gangs are rapidly evolving, becoming regional, national, and even international in terms of criminal operations. This globalization of gang-related criminal activity has been facilitated by improved technology, advancements in telecommunications, and increased mobility due to a vast and ever growing network of interstate highways and transatlantic airline flights. As a result, what once were neighborhood criminal gangs are now more organized gangs conducting criminal operations in multiple cities, states, and foreign countries. Some have evolved into transnational gangs that routinely conduct criminal activity that is planned in one country but executed in another country. After reviewing varying definitions and classifications of gangs, this entry focuses on the psychological control of gangs and the transformation of street gangs into transnational gangs.

Definition

There is no uniform definition of what constitutes a transnational gang or even a criminal gang. The definitions differ from state to state and from country to country. But, a *criminal gang* is generally defined as:

A group of three or more individuals, who have a common bond, establish territorial turf, and regularly conduct gang-related criminal activity.

In contrast, a *transnational gang* infers a much larger territorial turf that spans the borders of two or more foreign countries. The transnational gang is a sophisticated criminal enterprise that routinely plans and controls criminal activity in one country that is then executed in another country. Its criminal operations are global in nature, often spanning the borders of several international countries.

Classifications

First, Second, and Third Generation Gangs

For purposes of comparison, John P. Sullivan first classified criminal gangs into three separate categories. The first category, the *first generation gang*, is characterized as the traditional neighborhood or criminal street gang. It is local in nature, turf-oriented, and generally limited to a somewhat small geographic area. Its gang-related criminal activities, membership, and organizational structure are also limited. For the most part, the criminal activities are opportunistic, individualistic, and unorganized. Generally, the criminal activities include localized drug trafficking, extortion, burglaries, robberies, battery, petty theft, and murder.

The *second generation gang* is more evolved, more entrepreneurial, and enjoys more structured leadership than the first generation gang. A second generation gang is most often a well-established criminal street gang. Its criminal activities are organized, and the primary focus of the gang is financial gain, market share, and profit. Criminal operations, such as drug trafficking and extortion, are more complex and may span multiple municipalities, cities, or states. If the gang is located near a foreign country, the criminal operations may span international borders.

Due to the larger network of criminal activity of a second generation gang, leadership is more defined. It often has a set of rules and regulations, requires an oath of loyalty, and administers punishment for disobedient gang members or disrespectful rival gang members. The initiation phase most often includes a “blood in, blood out” loyalty pledge whereby the only way out of the gang is death.

The second generation criminal gang provides not only a sense of family and belonging but also a means of financial support. In many instances, it is the gang member’s source of income, family, and personal life—all rolled into one. It represents the essence, if not the totality, of the gang member’s existence. As a result, members of a second generation gang are willing to make extreme personal sacrifices and resort to acts of violence if threatened by a rival gang or a local law enforcement agency.

As the second generation gang grows, members are likely to establish business connections and alliances with other criminal gangs. If the second generation gang is located near an international border or a major drug trafficking route, its members may also establish alliances with drug cartels or more sophisticated third generation gangs. Once established, these alliances serve to accelerate the evolution of a second generation gang into third generation gang status.

The *third generation gang* is characterized as an international criminal enterprise. It routinely plans and controls criminal activity in one country that is executed in another country. Most often, it has extensive resources, controls international criminal operations, and is highly structured. Because of the magnitude and scope of criminal operations, the third generation gang has enormous power, not only financially but also politically. It is capable of infiltrating, corrupting, and controlling local governments.

Transnational Criminal Gangs

The third generation gang is also known as a *transnational gang*. Due to the highly organized nature of its criminal operations, the transnational gang is capable of overpowering less powerful gangs in order to gain market share, expand drug trafficking routes, and control larger geographical

territories. In addition, transnational gangs are able to engage in mercenary operations that openly threaten local governments, law enforcement agencies, or rival gangs that interfere with gang-related criminal operations.

As a result, the transnational criminal gang exerts control over residents, business operations, and traditional forms of government that operate within its territorial boundaries. To maintain power and control, the transnational gang is often willing to resort to extreme acts of violence. These acts of violence may include torturing, burning, or decapitating rival gang members as well as law enforcement officers, government officials, and judges.

In most instances, the transnational gang is well established, well financed, and highly structured. The gang is willing to use violence to maintain control and often recruits members who have military backgrounds or training in firearms or explosives. In turn, this paramilitary organizational style often attracts extremely vicious individuals who are willing to break the law and commit acts of violence in order to further the interests of the transnational gang.

Because of its size and scope of criminal operations, the transnational criminal gang is able to assemble large numbers of gang members from different states or countries if threatened by a rival gang, law enforcement officers, or local governments. To complicate matters, local government officials or law enforcement officers may be on the payroll of the transnational gang. As a consequence, some transnational gangs are being labeled *strategic threat groups* (STGs) by the state or foreign country where the transnational gang operates. El Salvador, for example, has gone even further by declaring Mara Salvatrucha (MS-13) and 18th Street Gang as terrorist organizations.

STGs

The term *STG* is generally reserved for gangs or criminal enterprises that are sufficient in size and power to pose a threat to correctional institutions, towns, cities, or foreign governments. They may include prison gangs, transnational gangs, or any gang that is strong enough to act as a de facto form of government that exerts control on smaller gangs, law enforcement agencies, local

governments, or individuals residing within its area of territorial control. Because of their power and size, STGs operate with impunity alongside more traditional forms of government. The STGs may even be so powerful that local law enforcement agencies avoid interference with the STG operations.

In many cases, transnational gangs have become serious STGs. They frequently become financial, political, and criminal enterprises capable of displacing more traditional forms of government. In many cases, the transnational gang controls government officials or law enforcement officers through bribes and various forms of threats. In fact, the bribes may lead to protection of the transnational gang's territory by the local law enforcement agency.

In some cases, transnational gang leaders become warlords, or political powers, that control certain geographical areas. If this occurs, the transnational gang becomes a state within itself, without recognized borders, that has enormous financial and political clout, maintains an active asymmetric army of gang soldiers, and even collects *taxes* from local businesses. In such instances, the transnational gang is a serious STG, posing a threat to the local form of government.

Psychological Control Over Local Citizens

The transnational criminal gang is often the only viable means of income for local citizens. It offers a way out of poverty, or as stated by local citizens, *a better way of life*. The criminal gang may even be perceived as a Robin Hood that robs from the rich (i.e., the government) and gives to the poor. It provides social control, protection, employment, and stability that might not have been provided by more traditional forms of government. It becomes the *recognized* form of government that replaces the more traditional, local form of government. In essence, it becomes a quasi-state that establishes its own rules and regulations and operates with impunity, often coexisting with official and more traditional forms of government in the area.

In addition, the transnational gang may use other forms of coercion to control rival gangs, locals, and coexisting government. Such tactics might include

- bribery of government officials;
- use of firearms, explosives, and arson to overcome police and rival gangs;
- violence, brute force, and military tactics;
- terroristic forms of violence such as burning and decapitation; or
- torture to obtain information.

With such tactics, transnational gangs often operate with little or no concern about police or military interference. Government officials and law enforcement officers become corrupted by bribes or threats of violence. In extreme instances, the government officials or law enforcement officers may even become agents of the transnational gang that provide more formal means of protection for gang-related criminal enterprises.

Transformation of Neighborhood Gangs Into Transnational Criminal Gangs

MS-13 is an example of a street gang that evolved into a transnational criminal gang. It was created in the 1980s by Salvadorians who fled El Salvador's civil war to Los Angeles, CA, but were persecuted and threatened by the well-established Los Angeles street gangs. Initially, MS-13 was a small, neighborhood gang. But, due to military training achieved during the Salvadorian civil war (1979–1992), the gang became known for ruthless acts of violence.

Today, MS-13 accepts members from El Salvador, Mexico, Central America, and parts of South America. The only requirement is military-style training and the willingness to commit acts of violence on behalf of MS-13. With this mentality, MS-13 has grown from a neighborhood street gang into a transnational gang that conducts criminal operations in Mexico, El Salvador, Guatemala, Honduras, Colombia, and other Central American countries.

This growth, in only 35 years, is due in part to the deportation of undocumented MS-13 gang members from the United States. Once deported, the MS-13 gang member establishes a new gang set. Often, this gang set is located in a less developed country with little training or resources allocated to combat the highly structured and highly organized transnational gang. In addition, the

newly formed MS-13 gang set maintains contact with fellow members in the United States through the Internet, social media, and cell phones. This serves to fuel the spread of drug trafficking and other internationally based criminal operations.

The evolution of MS-13 is not unlike other transnational gangs. One of the first street gangs in the United States to be classified as a transnational gang was the 18th Street Gang. It emerged in the late 1960s when the Los Angeles-based Clanton Street Gang refused to admit anyone to membership who was not of 100% Mexican ancestry. For protection, mixed-race Mexicans and non-Mexicans joined together to form the 18th Street Gang. Because the 18th Street Gang accepts persons of mixed racial and ethnic backgrounds, it rapidly grew in membership, power, and reputation for violence. It has grown from a neighborhood street gang into a transnational criminal gang with criminal operations spanning all 50 states, Mexico, Central America, and parts of South America.

The Future of Transnational Criminal Gangs

The future of transnational criminal gangs is uncertain. Admittedly, advancements in technology, social media, the Internet, and telecommunications have fueled the growth of regional, national, and transnational gangs. Gang-related criminal activities that once were limited to local neighborhoods now span not only state but also international borders. As a consequence, criminal gangs are rapidly evolving from localized, neighborhood street gangs into regional, national, and even transnational criminal gangs.

The next stage of evolution most likely will be related to future advancements in technology, communications, social media, and the Internet. With such advancements, more organized gangs such as national and transnational gangs are likely to engage in more virtual crimes. They are also likely to engage in highly profitable forms of cybercrime such as human trafficking, pornography, credit card fraud, and possibly cyberterrorism.

TRAUMA, TREATMENT OF

Justice involved individuals appear to have experienced a disproportionate amount of childhood maltreatment and trauma compared to the general population. They also present with significantly more mental health needs and by definition struggle with adapting to social and behavioral norms. Experience of witnessing and involvement in crime, and the criminal justice system itself (e.g., imprisonment), can also often be experienced as traumatic and can add to the overall cumulative impact of trauma within an offending population.

Although trauma is not currently considered a primary criminal risk factor, trauma and crime are inextricably linked, and this entry attempts to explore some of those links in more detail. The entry provides a brief overview of trauma theory and explores the links between trauma and crime, particularly recognizing the impact of trauma on the developing brain, emotional management skills, models of relationships, and behavioral control. The utility of rigid categorical and

diagnostic models of understanding and addressing offending behavior are explored, and the importance of a psychologically informed intervention approach that recognizes and addresses the developmental experience and environmental influences (including trauma) on the development and maintenance of criminal behavior is highlighted.

Brief Overview of Trauma Theory

Traumatic experiences are relatively common in the general population and can include neglect, physical and sexual abuse, exposure to domestic or community violence, accidents, war, and traumatic bereavement. While not all trauma survivors will experience long-term negative impacts (indeed due to a process of *post-traumatic growth*, some may well function better following a traumatic experience), those who experience severe or multiple traumas, particularly in childhood, are likely to be at greater risk of experiencing negative psychological, physiological, and behavioral consequences (including involvement in crime) over their lifetime. This includes an increased risk of displaying reactive aggression (it is thought due to high anxiety and easy triggering of the fight-or-flight response) and an increased risk of substance use, often with the explanation that the substances are used, at least in part, to experience relief from symptoms of trauma.

As a testament to our evolutionary foundations and our highly effective ability to adapt to often-extreme conditions, all humans are born *unfinished* in terms of the wiring of our brain. Although our genetics may provide a blueprint, it is the interaction of our genes with our experience that informs the development of our brain, in a highly adaptive way, to maximize our chances of survival. In simple terms, our brain can be understood to have three distinct parts that have evolved over millions of years to keep us safe and help us to thrive as a species. The most primitive part of our brain, the *old* brain, is involved in managing very basic core functions such as our metabolism, breathing, and heart rate. The second part, the *emotional* brain, is largely unconscious, irrational, impulsive, powerful, and self-centered. It is associated with our raw drives and core emotions and is involved in detecting threat in the

environment (our alarm system) and core survival responses (fight, flight, and freeze). These three instinctive survival behaviors have evolved adaptively to give us the best chance of survival under threat. The final part of the brain is the *thinking and social* brain (cortex) and is bigger and much more advanced in human than in most other animals. It is this part of our brain that allows us to think about consequences, problem-solve, regulate our emotions, inhibit our behavior, use language, store coherent memories, and understand the emotions and feelings of others. It is largely this part of the brain that is our *personality* and makes us who we are.

It is thought that through the experience of early relationships with caregivers (attachment) and our experience of threat and stress, that our brain wires, in an adaptive way, to maximize our chances of survival. Our early attachment relationships with caregivers help us to develop our model of relationships, ourselves, others, and the world. They underpin our self-esteem, our ability to seek and receive support from others, our ability to recognize and regulate emotion, and our ability to experience a sense of safety and security. When these early attachment relationships are disrupted, inconsistent, neglectful, overbearing, or at worst outwardly hostile, the core ability to regulate emotion and behavior and our ability to empathize with others is negatively (but arguably adaptively) affected, and these effects, unless addressed, may have lifelong consequences.

In addition to our early relational experiences, there is growing evidence of the negative consequences of traumatic stress on brain development, particularly in childhood. High levels of traumatic stress in early childhood can result in the stress response system remaining on high alert and can, at the most extreme, affect the development of the brain.

When we experience threat, our instinctual alarm system (based in the emotional brain) prepares us for survival action—often characterized by fight, flight, or freeze. When we experience trauma, the emotional brain is prioritized, and the capacity of the thinking brain (and the storage of coherent memories) is reduced. In effect, the more frightened (or emotional) we get, the less rational we are and the more instinctual our responses (e.g., fight, flight, and freeze). In addition, the

brain is not focusing on storing and processing memory, it is more interested in staying alive. As such, when our brains are overwhelmed with fear, our capacity for thinking, problem-solving, and processing coherent memories is reduced, and the resultant stored information becomes fragmented. It is these fragmented memories that are hypothesized to return as physical sensations, flashbacks or *intrusions*, nightmares, or behavioral reenactments. Such symptoms, along with avoidance and high levels of alertness (or hypervigilance) to threat, are associated with a diagnosis of post-traumatic stress disorder (PTSD).

Trauma, Crime, and Intervention

As indicated earlier, individuals involved in the criminal justice system appear to have experienced disproportionately more trauma than those in the general population. Many also have disrupted and chaotic early interpersonal and relationship (attachment) experiences. As such, they are at increased risk of reacting to a situation in survival mode (flight or fight) and disproportionately less able to regulate their behavioral and emotional response. They are also susceptible to behavioral reenactments of their traumatic experience.

One way of understanding an individual's response to trauma is through the concept of PTSD. Criteria for diagnosis of PTSD include exposure to (or witnessing) a traumatic event that results in significant distress and includes symptoms such as reexperiencing of the event (e.g., intrusive memories or flashbacks), negative cognitions and feelings, avoidance, and high arousal.

Following traumatic events, it is important not to pathologize any individual's response but to remain vigilant to the risk of the development of psychological difficulties and offer support where required. It is important not to undermine any existing positive coping mechanisms or social support and *watchful waiting* for a short period following a specific traumatic incident is often advisable. It is also the case that some people, while recognizing the event itself as being negative, report some positive consequences of experiencing traumatic life events, often termed *post-traumatic growth*; however, the nature of people's response to traumatic events is complex and often does not

follow a set pattern. The negative impact of traumatic experiences can be subtle and remain hidden for long periods, and the manifestation of difficulties may or may not be triggered by events or experiences in the future. There is also some emerging evidence that hints at the crucial role for the accumulation of stressors throughout life in shaping post-traumatic stress responses.

In the general population, PTSD is usually treated within an individually focused, phased-based therapy approach. Phases include the following: education about the impact of trauma and responses to it; building strategies to regulate distress and coping skills; reprocessing traumatic memories; acceptance; dealing with loss; and creation of a future template. Trauma-focused cognitive behavioral therapy (CBT) and eye-movement desensitization reprocessing therapy are two often recommended psychological treatments of choice and have been shown to have evidence of effectiveness within a general population.

However, while many of those within the criminal justice system may meet the criteria for a diagnosis of PTSD, it is increasingly recognized that categorical and diagnostic understanding of the response to traumatic experience and associated criminal behavior may be an oversimplification and can lead to ineffective or incomplete interventions that do not take into account the developmental and environmental experience of the client. The concept of *complex developmental trauma*, which recognizes the developmental impact of the client's attachment and trauma experiences, the client's relational environment, and the impact of the current situation on their presentation, is one that has growing importance and credence in clinical practice, and especially within criminal justice settings.

Such trauma-informed intervention approaches require a move away from the diagnostic and categorical nature of understanding an individual's distress and resulting behavior. Categorical approaches can lead to the overly simplified *prescription* of psychological intervention driven by either the labeling of the offense (e.g., an individual committing a violent offense is *treated* with a violent offender program) or the diagnosis (e.g., post-trauma experiences are treated with CBT). Such approaches continue, however, to be regularly observed in clinical practice within justice settings,

even though they often can have little impact when used as single, isolated interventions with individuals presenting with complex presentations.

An alternative approach is one based on psychological formulation and underpinned by a comprehensive psychological assessment and formulation of needs and risk that is multifactorial (e.g., not based on one theoretical perspective and incorporates psychological, social, criminological, and biological understanding) and multisystemic (e.g., considers the intervention and individual within developmental, relational, and environmental systems). Such an approach recognizes the complexity involved in understanding offending behavior within the context of personal experience and trauma (and mental health more broadly), and takes into account developmental factors, timing, pace, and dosage of the intervention. It places great emphasis on the dynamic nature of the therapeutic process, regular monitoring of change and subsequent review, and reformulation of needs and the intervention. Trauma-informed approaches also recognize the central importance of positive, nurturing relationships in supporting trauma resolution and behavior change. The development of a therapeutic environment that is safe and conducive for change, including effective risk management and strong, developmentally attuned relationships are thought to be key in enhancing effectiveness.

Such multisystemic formulation-based interventions are likely to be multifaceted and intensive and may often (but not always) include traditional evidence-based individual trauma therapy (e.g., CBT, eye-movement desensitization reprocessing therapy) as one aspect of support. Formulation-based approaches would also encourage other areas of intervention, such as enhancing the relationships with professionals, partners, or family, and helping the individual to find safe accommodation and engage in positive activities or education. The formulation may often indicate prioritization of certain interventions, in recognition of the developmental course of the therapeutic process. For example, asking a young traumatized client to reprocess traumatic memories before he or she had developed the skills to manage high levels of emotional distress, may only serve to increase risk and retraumatize the

individual. This can be particularly harmful if done in a correctional environment where the individual may be more susceptible to further traumas. In this case, work with the individual's caseworker to support emotional regulation would be prioritized over direct trauma-focused work.

In summary, many of those who offend are likely to have experienced trauma in the context of other negative developmental experiences. Understanding the impact of these experiences on the developing individual, while obviously not condoning offending behavior, suggests that our personal experience (including social, biological, environmental, and psychological influences) is inextricably linked with our behavior. In other words, our thoughts, feelings, and behaviors are all complexly linked and exist within the context of our developmental experience, response to trauma, and physical and relational environment.

Therefore, while individual therapies (e.g., CBT or eye-movement desensitization reprocessing therapy) may be extremely effective components of an intervention addressing complex trauma (and arguably criminal behavior) within an offending population, such interventions may be ineffective in isolation. To maximize effectiveness, they need to take into account and are likely to be enhanced by a developmentally informed, multisystemic, multifactorial, formulation-driven approach to care. An understanding of the role of early attachment and trauma and a client's development, personal experience, and relationships is recognized as invaluable and arguably an essential component of *any* assessment and intervention with traumatized clients who display high-risk and offending behavior.

TRAUMA-FOCUSED COGNITIVE BEHAVIORAL THERAPY

Cognitive behavioral therapy is an evidence-based treatment approach and has been the focus of much research in its application to trauma-related disorders. The application of cognitive behavioral therapy in addressing trauma is based on two major theories: learning theory and cognitive theories. *Learning theory* includes the concepts of classical and operant conditioning. *Cognitive theories* address the impact that core assumptions and beliefs have in the development and preservation of trauma-related disorders. This entry discusses variations of trauma-focused cognitive behavioral therapy.

Trauma-focused cognitive behavioral therapy seeks to address the cognitive and behavioral reactions to experiencing trauma. The cognitive

reactions to trauma often include maladaptive cognitions about the traumatic event and its aftermath. Other cognitive reactions may include impairment in an individual's ability to recall memories regarding the trauma and/or development of strong associative memories with the trauma. Trauma-focused cognitive behavioral therapy may be used to treat a variety of individuals within the criminal justice system, including offenders, victims, judges, victims' advocates, and law enforcement personnel.

Trauma-focused cognitive behavioral therapy encompasses a variety of procedures and involves variations of psychoeducation, exposure, cognitive restructuring, and anxiety management. Exposure therapies include systematic desensitization, prolonged exposure, and eye movement desensitization and reprocessing (EMDR). Stress inoculation training (SIT) is a type of psychoeducation. Another variety includes a combination as seen in cognitive processing therapy, which is a manualized approach involving cognitive restructuring and prolonged exposure. Psychoeducation and anxiety management are more common with the offender population than are exposure therapies. Exposure therapies are more common with the victims and workforce populations of the criminal justice system. There are several reasons for the variation in approaches with the different populations of the criminal justice system. These include public perception, stigma, motivation, and funding.

Psychoeducation

The goal of psychoeducation is to provide individuals with information on stress reactions and management. Donald Meichenbaum developed SIT. The goal is to assist an individual in understanding and managing his or her reactions to a trauma that results in behaviors driven by fear. There are three stages within SIT: education, skill building, and application.

Exposure

The goal of exposure therapy is to assist the individual in reducing the distress experienced when exposed to aspects of the trauma, such as thoughts, feelings, or situations. Prolonged exposure therapy

consists of four parts: education, breathing, real-world practice, and talking through the trauma. Systematic desensitization involves a graduated exposure process through a hierarchy of fears. Joseph Wolpe identified three steps: (1) create a hierarchy of fears; (2) learn a coping mechanism; and while engaged in the coping mechanism, (3) the individual is exposed to the identified fear stimulus.

Francine Shapiro developed EMDR. It operates on the basis that the trauma was not properly encoded into the individual's memory. This prevents the individual from integrating the trauma and results in trauma-related symptoms. EMDR integrates the trauma through bilateral stimulation. There are eight phases to EMDR: client history phase, preparation phase, assessment phase, desensitization phase, installation phase, body scan phase, closure phase, and reevaluation phase. Initial research studies have been completed utilizing EMDR with incarcerated individuals.

Cognitive Restructuring

Cognitive restructuring is used to challenge the maladaptive cognitions that an individual develops related to the trauma and its aftermath. Common maladaptive cognitions include distorted perceptions of blame and guilt that the individual could and should have done more to prevent the trauma.

There are four steps in cognitive restructuring. Step 1 is to identify the distressing situation. Step 2 is to record negative thoughts or feelings regarding the distressing situation, also referred to as *automatic thoughts*. Step 3 is to identify distortions in the negative thoughts or feelings and substitute them with rational responses that contradict the negative thoughts and feelings. Step 4 is to reevaluate the belief in the original negative thoughts and feelings.

Anxiety Management

Anxiety is a normal reaction following a trauma. However, anxiety can easily become overwhelming, resulting in a loss of functional activity. The individual's automatic thoughts as discussed in cognitive restructuring can serve to exacerbate and maintain the anxiety.

Anxiety can present in a number of ways following a trauma: isolation, fear of doing things, fear of situations that remind the individual of the trauma, repetitive behaviors, hypervigilance, and physical complaints, such as gastrointestinal problems, headaches, and muscle aches. Anxiety may impact various parts of the individual's life (e.g., work, interpersonal relations) and can cause changes in personality (e.g., aggressive or self-destructive behaviors). There are several methods by which an individual can manage anxiety. These include journaling, the use of distractions, relaxation strategies, memory creation, yoga, sleep, eating healthy, and exercise.

Combined Approaches

Cognitive processing therapy is a manualized therapy used in the treatment of post-traumatic stress disorder that combines cognitive restructuring and prolonged exposure. The goal is to raise awareness on how experiencing trauma changes an individual's view of the world. There are four parts to cognitive processing therapy: education regarding trauma-related symptoms, becoming aware of thoughts and feelings, learning skills that challenge thoughts and feelings, and learning about changes in beliefs following exposure to a trauma.

Other combined approaches include addressing concurrent substance abuse and trauma-related symptoms. One model is the Addiction and Trauma Recovery Integrated Model developed by Dusty Miller and Laurie Guidry. Addiction and Trauma Recovery Integrated Model assists individuals in understanding the impact of trauma and addiction on their physical, mental, and spiritual health. A second model is seeking safety, which assists individuals in finding safety in relationships, thinking, behavior, and emotions. A third approach is substance dependence post-traumatic stress disorder therapy, which has two phases. Phase 1 is trauma-informed, addiction-focused treatment that incorporates coping skills and cognitive interventions. Phase 2 is trauma-focused, addiction-informed treatment that includes psychoeducation and SIT.

TRAUMA-INFORMED TREATMENT

Trauma-informed treatment refers to an approach in the provision of mental health services, which takes into consideration an understanding of trauma and its impact across multiple settings, not just its impact on the individual. Trauma has a rippling effect that impacts those around the individual, including friends, family, coworkers, and communities. This may even have cultural and generational impacts. Within the criminal justice system, trauma may be present among several groups of individuals who could benefit from trauma-informed treatment. The most commonly acknowledged and understood group are the victims of crimes. Other groups that may experience trauma include offenders, judges, victims' advocates, and law enforcement personnel. It is not uncommon for offenders to have experienced multiple traumas prior to their involvement with the criminal justice system. Experiences while incarcerated can also be traumatic. This entry discusses what trauma-informed treatment is, common interventions, co-occurring disorders with trauma, and trauma-informed case conceptualization.

Trauma-informed treatment seeks to address six important principles. The first principle is safety. Safety encompasses several elements including

safety from the trauma and safety from self-destructive behaviors. An example of safety from the trauma may be leaving an abusive relationship; an example of safety from self-destructive behaviors may be letting go of the idea of suicide as an option. A second principle is trustworthiness and transparency. It is important for the individual seeking treatment to feel he or she can trust the mental health provider without concerns about hidden agendas. The third principle is peer support. By seeking support from peers, a sense of normalcy and connection is established. Peer support provides a nonclinical perspective to the trauma. Collaboration and mutuality is a fourth principle. Within trauma-informed treatment, the mental health provider empathizes and collaborates with the individual to address reactions to the trauma. Collaboration also empowers the individual, the fifth principle. During and/or following a traumatic event, an individual often experiences loss of control. A part of treatment is helping the individual to become empowered and find his or her voice again. The final principle addresses issues related to culture, history, and gender. By looking at culture, history, and gender issues, an individual can begin to understand the interaction with his or her reaction to the trauma and begin the process of integrating the trauma into his or her life.

Trauma

Not all individuals react to situations in the same way. An event that may be traumatic for one individual may not be for another. Some individuals may have an acute reaction to the trauma, such as acute stress disorder, while others may develop a more chronic reaction, such as post-traumatic stress disorder. It is important to remember that individuals respond to experiences in their own unique ways.

Trauma can impact individuals of all backgrounds, races, genders, and ages. Trauma may be a single event, a series of events, or set of circumstances. It impacts an individual's ability to cope emotionally and physically. Some situations that may be viewed as traumatic events include physical, sexual, or emotional abuse; neglect; family dysfunction; accidents, unexpected deaths, illness, surgeries, and disabilities; natural disasters (e.g., earthquakes, fires, floods); and war or acts of terrorism.

Trauma-Informed Interventions

Trauma-informed interventions seek to prevent retraumatization of the individual and the development of mental health disorders and seek to promote resiliency. The promotion of resiliency is achieved through psychoeducation and the development of adaptive coping mechanisms.

Trauma-informed interventions are divided into two categories: interventions provided within the first 48 hr following a trauma and interventions following the immediate response. These interventions are often seen in work with victims and law enforcement personnel. Interventions provided within the first 48 hr include basic needs, psychological first aid, and critical incident stress debriefing. *Basic need interventions* include ensuring basic necessities are met, such as water, shelter, and food. *Psychological first aid interventions* provide emotional support immediately following a trauma. Mental health providers engaged in psychological first aid facilitate communication with individuals and seek to identify individuals demonstrating reactions that may put them at a higher risk of developing a trauma-related disorder. *Critical incident stress debriefings*, developed by Jeffrey Mitchell and George Everly, are facilitator-led groups designed to engage individuals involved in a traumatic event to talk about their experiences. The aim is to provide psychological closure to the event. The groups also have a psychoeducational component, providing information on stress reactions and management.

Interventions following the immediate response to a trauma include cognitive behavioral therapies, cognitive processing therapy, exposure therapy, eye movement desensitization and reprocessing, narrative therapy, skills training in affective and interpersonal regulation, and stress inoculation training. The interventions available to offenders within the criminal justice system are minimal and are often limited to cognitive behavioral therapies. There are also integrated interventions that address both trauma and substance abuse.

Co-Occurring Disorders With Trauma

There is a correlation of trauma with other disorders, including substance abuse disorders

and mental health disorders. The correlation between trauma and substance abuse is viewed as bidirectional and cyclical. Exposure to trauma may increase substance use in an effort to manage symptoms (*self-medication hypothesis*), while substance use may increase an individual's risk to trauma (*high-risk hypothesis*). Howard Chilcoat and Naomi Breslau also identified a third hypothesis, the *susceptibility hypothesis*, which suggests that individuals who use substances are more susceptible to developing post-traumatic stress disorder following exposure to trauma. The majority of individuals incarcerated have a substance use disorder. Programs within jail and prison settings often only address the substance abuse side of the problem, overlooking the interaction between substance abuse and trauma.

The presence of mental health disorders is also prevalent among individuals who are incarcerated. Mental health disorders that co-occur with trauma include major depressive disorder and anxiety disorders. Edna Foa and colleagues established a causal relationship between depression and traumatic events, stating that a prior history of a major depressive disorder is predictive of an individual developing post-traumatic stress disorder following a trauma. Anxiety disorders may be exacerbated by the trauma, and/or the anxiety disorder may increase an individual's vulnerability to developing post-traumatic stress disorder following a trauma.

Trauma-Informed Case Conceptualization

In providing trauma-informed treatment, the mental health provider must be able to conceptualize the case from a trauma-informed perspective. A trauma-informed case conceptualization has five components. First, the individual is viewed from the perspective of being scared, sad, or angry versus being bad. The individual is not viewed as damaged or broken. Second, the individual's problems are externalized, while acknowledging that the individual's resiliency is internal. A third component normalizes the problem and the solution. Emphasis is given not to pathologize either. The fourth component is identifying the individual's strengths and resources. The final component within the case conceptualization is mobilizing the

individual to engage in activities that are productive within the treatment process.

TRAUMATIC BRAIN INJURY IN INCARCERATED OFFENDERS, TREATMENT OF

A range of studies has indicated possible links between traumatic brain injury (TBI) and offending. In general, the consequences of brain injury may include poorer cognitive skills (memory, concentration, planning), decreased awareness of one's own or others' emotional state (including empathy), poor behavioral control (impulsivity, irritability), and particularly, poor social judgment. Indeed, sociobehavioral problems are common, such as being less able to de-escalate threats and acting without considering consequences of action. Moreover, it is likely that problems with attention, memory, and executive functions would limit capacity to fully engage in forensic rehabilitation to enable behavior change, such as the ability to pay attention, remember, and follow through on advice about new ways to manage a problem situation. This entry begins with a brief overview of brain injury, explores the role of TBI in offending, and reviews various forensic rehabilitation approaches.

Brain Injury

Brain injury is the major cause of death and disability in children and young adults. Brain injury may occur for many reasons, including trauma, infection, and stroke; however, trauma is the most common cause of brain injury. TBI affects around 8.5% of the population, but prevalence of TBI is much higher among certain populations, such as those involved in contact sports, victims of domestic violence, and adolescent males who consume alcohol.

Studies have shown that the frontal and temporal areas of the brain, the areas important for decision-making and managing emotion, are the most common sites of injury. TBI may be classified from *mild* to *severe*. A very mild injury—typically referred to as a *concussion* (i.e., some disorientation or confusion at the time but no loss of consciousness)—rarely leads to permanent brain changes. However, with greater signs of *dosage*, such as being knocked out for a longer period of time and/or a deeper level of unconsciousness, actual changes in the brain can be expected.

Most TBIs are classified as mild (80%), and 85–90% of those with a mild TBI are expected to recover fully (or near fully). In mild forms of TBI, there can still be disruption to these connections across the brain—especially in adolescence. However, outcomes after brain injury in children and young people are hard to quantify or predict because their brains are undergoing change. To some degree, the brain's ability to adapt to injury (neuroplasticity) confers some protection of functions but may also mean there is less capacity for other functions to develop (i.e., *crowded out*). It is important, therefore, to be mindful of a need for monitoring for problems that might be expressed over time, particularly of abilities that may have been developing at the time of injury.

Furthermore, mental health problems, especially anxiety and depression, are also common after TBI. Survivors are often unable to return to school or work successfully, have problems in forming and maintaining relationships, and experience family and social disruption. The net effect of such stresses and strains is that severe mental health disorders, with a high risk of suicide, are common.

Brain Injury and Criminal Justice

Longitudinal studies have shown a link between TBI and later offending, even when controlling for socioeconomic background and genetics. Studies of groups of young offenders also seem to indicate a specific contribution that TBI can make to increasing the risk of offending over a lifetime as well as increasing the severity of the crime (e.g., violent crime).

What is also now well established is the very high rate of TBI in people who are incarcerated and that TBI within offenders appears to be a risk factor for future crime (i.e., recidivism). Globally, studies notably in Australia, Brazil, Canada, France, New Zealand, the United Kingdom, and the United States have shown that the prevalence of TBI is 3–8 times greater in people in custody compared to nonoffenders. In 2013, Thomas J. Farrer and colleagues conducted a meta-analysis of nine studies involving TBI in juvenile offenders, five of which included control groups of nonoffending youths. The prevalence rate was approximately 30%, which was significantly higher than in the control groups. In a 2015 systematic review, Nathan Hughes and colleagues looked at 10 studies (some overlapping with Farrer's meta-analysis) and reported prevalence rates of TBI among incarcerated youths ranged from 16.5% to 72.1%. Where there were control groups or directly comparable studies within the general population, there was consistent evidence of a higher prevalence of TBI among incarcerated youths, and this disparity was more pronounced as the injury severity increased.

TBI in offenders, mostly in studies with adults, has been associated with higher rates of infractions while in custody and higher levels of reoffending and engagement in violent crimes. One study represents a range of these issues. In 2010, Huw Williams interviewed 197 young male offenders in a prison about head injuries, their crime history, mental health problems, and drug usage. They were, on average, 16 years of age. Around 60% reported some kind of *head injury*, but, importantly, TBI with a loss of consciousness was reported by 46% of the sample. The main cause of injury in the young was violence. Repeat injury was common: One third reported being *knocked out* more than once. Self-reporting three

or more TBIs was associated with greater violence. Those reporting TBI were also at risk of greater mental health problems and misuse of cannabis. In a related 2012 study, Rebecca C. Davies and colleagues found a relationship between TBI and current concussion symptoms: Those with more serious mild injuries reported a greater degree of ongoing problems compared to those reporting less or no loss of consciousness. This indicates that those with TBI are likely, depending on the severity of injury, to have brain injury–related problems that may interfere with forensic rehabilitation.

Forensic Rehabilitation and Neurorehabilitation (NR)

In several countries, including the United Kingdom, a number of approaches have been developed that have led to improvements in offenders' well-being and crime reduction.

The Risk-Need-Responsivity approach takes into account the risk of reoffending, criminogenic needs, and psychological preparedness to respond to interventions including cognitive behavioral interventions. Cognitive behavioral therapy is consistently associated with improved institutional behavior, lower recidivism rates, and a longer time to rearrest. These types of approaches are not necessarily routinely or widely available though. Moreover, these types of interventions may not work effectively with people with TBI.

NR encompasses a range of approaches for improving the quality of life for individuals with brain injury. NR is a process by which a person with brain injury may identify life goals he or she may achieve with guided support, get around deficits he or she has acquired with strengths that he or she may still have, and develop new strategies the person finds helpful in managing cognitive, emotional, and behavioral problems. Evidence shows that it is possible to address and manage underlying cognitive impairments such as attention, memory, and executive functions and improve outcomes for emotional distress, behavioral problems, and socialization.

Cognitive NR is the main form of NR. There are two main approaches: compensatory and restitution. The compensatory approach involves improved functioning in everyday life by using aids or strategies that compensate for a deficit, such as

a memory aid (e.g., diary or smartphone prompt) or a mnemonic strategy (e.g., using paced rehearsal). Restitution involves restoring normal functioning through repetitive practice (e.g., computerized cognitive training packages). There has been significant work in the area of NR that indicates that it can be helpful for changing behavior. The Scottish Intercollegiate Network (SIGN) guidelines and the INCOG, international Cognitive guidelines (developed by an international group of researchers and clinicians) provide evidence to underpin practice—these are summarized in the following subsections.

Memory

Memory deficits are the most common aftereffects of brain injury. SIGN noted support for compensatory approaches, including memory strategy training and electronic aids such as personal digital assistants. SIGN recommended memory impairment rehabilitation and supported the integration of internal and external strategies when appropriate—with their use in social roles or everyday situations being prompted and supported.

Executive Function and Attention

Impairments in executive function and self-awareness are some of the most common effects of brain injury and can have a profound effect on resuming previous life roles. Training in metacognitive strategies is seen as effective at improving performance in practical or functional settings. Metacognitive awareness is a consistent theme in NR. A metacognitive strategy is to teach individuals to regulate their own behavior by breaking complex tasks into steps and considering possible solutions based on past experience and prompts.

The INCOG group noted that there is new evidence to support the use of strategies to improve reasoning skills and substantial support for the use of direct corrective feedback in improving self-awareness. With regard to attention, SIGN noted that evidence that impairment-focused training (e.g., computerized attention training) may produce small effects, but generalization was weak. However, larger effects are found when interventions focus on repetitive practice that compensates for attention impairments in everyday tasks.

Sociocommunication

Brain injury may result in a variety of communication impairments (e.g., dysarthria or poor clarity of speech, reduced use of facial expression, poor eye contact, poor listening skills, a reduced ability to read emotional expressions). Several studies reviewed by SIGN suggest that language deficits and/or functional communication deficits can be treated (e.g., via expression modeling, pitch biofeedback, conversation group therapy).

Mood and Behavior

Individuals with brain injury will likely have some degree of comorbidity of conditions (e.g., they will present with TBI, anxiety, and alcohol abuse). Management interventions are not very advanced, but case illustrations and, increasingly, controlled studies indicate that interventions that combine cognitive behavioral therapy and NR can be effective. These approaches are *comprehensive* or *holistic* as they aim to simultaneously address cognitive, emotional, and behavioral problems, while returning the individual to meaningful activities. Crucially, therapies are modified to take account of the cognitive and self-regulatory deficits common in brain injury. SIGN noted that nonpharmacological interventions have been used for adults with challenging behaviors following brain injury. In one study, individuals with brain injury of mixed causes resulting in persistent aggressive behavior (leading to their being unable to live independently), SIGN resulted in more independent living, improved employment, and reduced hours of care at nearly 3 years' follow-up.

Vocational Approaches

SIGN has reported sufficient evidence to recommend holistic neuropsychological rehabilitation in terms of return to employment. In one study, of an intensive cognitive rehabilitation program, which consisted of 15 hr (of individual and group therapies conducted 3 days per week—with social problem-solving tasks to tackle individual problems) upon completion, 47% of participants were engaged in community-based employment compared to the 21% in the standard rehabilitation group.

NR and Children/Young People

There has been some work systematically examining the role of NR for children and young people. One interesting study in relation to crime was conducted in 2003 by Jose Leon-Carrion and colleagues who investigated whether adult prisoners with brain injury in childhood had received any form of NR. Those who had a brain injury and NR were more likely to be in prison for less violent offenses than those who had a brain injury but no NR.

Case Example

In 2016, Williams and Prathiba Chitsabesan reviewed a service setup to manage TBI in young offenders in custody. Service workers, known as *Linkworkers*, were employed to enable prison staff to better identify and help affected young people. With the benefit of Linkworkers, staff would be able to know when to use memory cues to assist young people to manage anger, feelings of suicidality, and alcohol and drug issues. For example, one young man was angry, aggressive, and noncompliant—including throwing food at staff. He had lost privileges and was at risk of being moved to solitary containment. The Linkworker performed an assessment that showed that the young man had a TBI that made him unable to remember instructions (as an assault from a parent had affected his left temporal lobe, the long-term verbal memory *store*). Staff were encouraged to use visual prompts to help the young man remember when his recreation time was, for example, and how many rewards he had gained. This helped him stabilize in mood and behavior. He was soon earning privileges and reinvested in education for gaining skills for resettlement into the community.

Conclusions

The evidence base of TBI is complex, and more evidence is needed regarding prevalence of TBI by sociodemographic characteristics, prevalence or impact of repeat experiences of TBI, and experiences of comorbidity of TBI and other developmental and mental health difficulties. Within custodial and/or probation systems, it is important for frontline staff to have sufficient knowledge of TBI and its consequences so that they may take

account of any TBI-based issues in their day-to-day management of offenders. Specialist training, advice, and support need to be provided when there is clear evidence of significant TBI-related behavioral and/or psychiatric needs. Justice system staff, both community and custody staff, require training in TBI assessment and management. Some offenders may need to access specialist neuropsychology assessments, such as those conducted by a clinical neuropsychologist or educational, clinical, and forensic psychologists. It is vital that services for offenders include packages of care that address the range of issues related to TBI.

TREATMENT DOSAGE AND TREATMENT EFFECTIVENESS

Treatment dosage refers to the amount of treatment required to produce a desired outcome. In correctional treatment, the desired outcome is typically reduced recidivism. Consequently,

correctional programs that reduce recidivism are characterized as effective programs. Research demonstrates that there is a significant relationship between the amount of treatment that an offender receives and whether he or she will reoffend. The relationship between treatment dosage and reduced recidivism is not as simple as continually increasing treatment dosage to produce larger recidivism reductions, however. The amount of treatment required to reduce recidivism depends on other factors such as the offender's likelihood of committing a future crime, what the offender is working on during treatment, and the type of treatment used by the correctional treatment program. This entry reviews various ways of measuring dosage, further examines the role of dosage in reducing recidivism, discusses the effective alignment of treatment dosage to risk to reoffend, and concludes with a look at ongoing research.

Measuring Dosage

There are several ways to measure dosage. The first is the length of stay in a program. In other words, dosage can be defined as the number of days that an offender spends in a program. The second is the number of treatment sessions attended, regardless of how many days an offender was in the program. For example, an offender might spend 30 days in a program that requires attendance at three treatment groups per day for 5 days per week. This equates to attendance at approximately 60 treatment sessions during a 30-day stay. The third is the number of hours that the offender spends engaged in treatment activities, regardless of both the total number of days spent in a program and the total number of treatment sessions attended. Measuring dosage in hours is the preferred method of measurement as it is more precise than length of stay or number of sessions attended. For example, two offenders can stay in a program for the same number of days but attend a different number of treatment sessions. In addition, the treatment sessions that they attend may not be of the same duration or length. In both of these examples, the total number of hours would differ even if the total number of days or the total number of sessions were the same.

Understanding Risk, Need, and Responsivity

To best understand the role of treatment dosage in reducing recidivism, one must first have an understanding of the larger scientific framework of evidence-based correctional treatment in which dosage is embedded. This framework comprises three guiding principles: the risk principle, the need principle, and the responsivity principle. The risk principle acknowledges that not all offenders pose the same risk to public safety. In other words, some offenders have a high probability of reoffending while others have a low probability of reoffending, or some are high risk and some are low risk. Consequently, the risk principle guides corrections staff to consider an offender's likelihood of committing future crime when assigning treatment and supervision resources so that high-risk offenders receive more treatment and supervision than low-risk offenders.

Research supports the risk principle by demonstrating that correctional programs are more effective with moderate- and high-risk offenders than they are with low-risk offenders. One reason for this is because moderate- and high-risk offenders have more room to improve than low-risk offenders. Research also shows that programs that intentionally target higher risk offenders for services and supervision are more effective at reducing recidivism than programs that target lower risk offenders. Perhaps most important, however, is that some research shows that when the criminal justice system targets low-risk offenders for intensive interventions, crime rates for these offenders go up rather than down. These findings demonstrate that higher risk offenders should receive a higher amount of treatment dosage than their lower risk counterparts and that correctional practitioners can provide too much treatment dosage to low-risk offenders.

While the risk principle tells practitioners who to prioritize for treatment services, the need principle tells them what to target during treatment. The need principle asserts that correctional treatment staff should spend more time targeting those offender needs that have been shown to be directly correlated to criminal behavior. These needs are often referred to as *criminogenic needs*. Examples of some of the needs more strongly related to

criminal behavior include endorsement of antisocial thoughts and attitudes, associating with antisocial peers, and the presence of a constellation of antisocial personality traits that include recklessness, self-centeredness, impulsivity, lack of coping skills, and lack of social skills. Other important criminogenic needs include substance abuse, unemployment, educational deficits, and lack of positive family and social supports. Research demonstrates that programs that spend the majority of their time working on these needs produce the greatest impact on recidivism. So while the risk principle tells practitioners to whom to apply higher levels of treatment dosage to reduce recidivism, the need principle dictates what needs should be targeted by that treatment dosage when the goal is to reduce recidivism.

The responsivity principle outlines factors that affect an offender's ability to respond to correctional interventions. There are two types of responsivity: specific and general. Specific responsivity refers to characteristics unique to an individual offender that may need to be addressed in order for him or her to benefit from correctional interventions. A few examples of specific responsivity characteristics include motivation for change, cognitive functioning, and mental illness. General responsivity, on the other hand, refers to the treatment modality or approach that works best for reducing recidivism for offenders as a group.

Matching Treatment Dosage to Offender Risk in Real-World Settings

As discussed earlier, programs that target higher risk offenders are more effective at reducing recidivism than programs that target lower risk offenders. Targeting higher risk offenders for inclusion in programming and supervision is only one necessary strategy for effective execution of the risk principle, however. To produce optimal results, practitioners must also effectively match the appropriate amount of programming and supervision to the risk level of the offender. This leaves correctional practitioners the task of quantifying the appropriate amounts of service to provide to offenders of varying risk. While dosage research continues to evolve, empirical guidelines suggest a minimum of 100 hr of evidence-based correctional treatment

for moderate-risk offenders and 200 hr of evidence-based correctional treatment for high-risk offenders.

Correctional programs must meet a number of requirements to effectively match treatment to risk and to avoid one-size-fits-all programming. First, the program must have a process to assess criminogenic risk and needs for all offenders entering the program using a validated risk assessment instrument shown to reliably predict recidivism. Second, the program must have policies, procedures, and treatment manuals that allow for variation in treatment dosage by risk. In other words, the program has to have the ability and resources to provide 100 hr of treatment to moderate-risk offenders while providing 200 hr of treatment to high-risk offenders. Third, the agency must use evidence-based treatment strategies with fidelity if time spent in treatment activities is to count as dosage. The number of treatment hours provided is irrelevant if the program is using treatment strategies that have not been proven to be effective. Finally, the program must have a way to record and monitor the amount of time that offenders spend in these activities in order to total how much dosage each individual offender receives while in the program. In sum, providing effective treatment dosage is more than simply counting the number of hours an offender has spent in treatment. For treatment to be effective, the correct amount of treatment dosage needs to be aligned with the offender's risk to reoffend, the treatment must target the offender's specific criminogenic needs, and the treatment must be delivered using an evidence-based model of treatment.

When discussing effective alignment of treatment dosage to risk to reoffend, a cautionary note about overtreatment is warranted. Current research clearly demonstrates that the effect of treatment dosage varies by risk and that continuing to increase dosage fails to produce a positive impact on recidivism for all risk groups at some point. For low- and moderate-risk offenders, research has shown that provision of too much treatment actually leads to increases in recidivism. For higher risk offenders, research has not yet identified the amount of treatment that might be expected to produce an increase in crime, but initial studies do suggest dosage amounts that fail to produce continued and meaningful reductions in

crime. In other words, there may be a saturation point, even for higher risk offenders, at which the continued provision of treatment fails to result in recidivism reduction.

Findings related to the effects of overtreatment have both fiscal and ethical implications. Corrections as a field has limited, finite resources; therefore, continuing to expend resources on providing increased dosage with no return on investment (as measured by reduced crime) does not represent prudent use of limited public funds. Similarly, continuing to provide high levels of dosage to lower risk offenders with a result of increased crime is harmful to public safety and, therefore, contrary to the mission of corrections agencies.

Ongoing Research on Treatment Dosage and Treatment Effectiveness

To continually improve the ability of correctional programs to best match type of treatment services and treatment dosage to each individual offender based on his or her specific criminogenic risk and needs, researchers and practitioners continue to collaborate on identifying and testing the most effective applications of treatment dosage. Examples of areas of continued joint investigation include (a) investigating effective dosage applications for female offenders compared to male offenders, (b) investigating effective dosage applications for specialty populations such as sex offenders or offenders with an opioid use disorder, (c) establishing guidelines for adjusting dosage protocols for individual offenders based on treatment progress or lack thereof, (d) identifying the appropriate sequencing of treatment targets during the course of care, and (e) determining the cumulative impact of dosage for individuals who have been in multiple treatment programs.

TREATMENT FOSTER CARE OREGON

Treatment Foster Care Oregon (TFCO), formerly Multidimensional Treatment Foster Care, is a community-based intervention program for children and adolescents who struggle with chronic and disruptive antisocial behavior, emotional problems, and (in the case of adolescents) juvenile delinquency. TFCO serves as an alternative to residential and group home placements for youth requiring out-of-home care and can also be used as a transitional placement for youth reentering the community from correctional facilities or other institutional settings. In TFCO, placements are short-term (typically 6–9 months), and youth are placed individually in supported foster homes. This entry describes TFCO’s foundations, treatment model, program outcomes, and adaptations within and beyond the juvenile justice setting.

TFCO Foundations

This section begins with a brief review of the historical context that contributed to TFCO’s development as a community-based alternative to institutionalization. It then explains how social learning theory informs the TFCO model.

Historical Context

TFCO was initially developed in response to changing needs within the Oregon juvenile justice system. In the early 1980s, Oregon’s rate of incarceration for juvenile offenders was relatively high compared to other states. Youth with a history of delinquency or behavioral problems were typically sent to state *training schools*, which served as residential correctional facilities for youth with varying levels of criminal involvement and mental health problems. Improved understanding of the potentially detrimental impacts of institutionalization on adolescents led to a shift toward community-based interventions. In 1983, Patricia Chamberlain and colleagues received state funding to develop a community-based alternative for youth who were committed to, then diverted from, institutional settings. This program, which would later be known as TFCO, was first provided to juvenile offenders, then expanded in 1986 to include youth transitioning out of state mental hospitals. By the 1990s, the number of TFCO cases continued to diversify and increase, and participants included youth referred by juvenile justice, mental health, and child welfare services.

Theoretical Model

The TFCO model is rooted in social learning theory, which emphasizes that learning takes place in a social context and is influenced by cognitive, behavioral, and environmental factors. Individuals learn to behave through observation and role modeling of others’ responses to the environment and, in turn, influence that environment through their own behaviors. For example, a youth may be more at risk of engaging in problem behavior or delinquency if his or her environment includes low adult supervision, lack of consistent discipline, and friendships with delinquent peers. The youth’s behavior

may also contribute to an increased sense of conflict at home, which may decrease parents' abilities to effectively supervise and discipline. The youth finds increased support from delinquent peers who in turn reinforce problematic behaviors and alienation from supportive adult influences. Eventually, the youth's behavior becomes chronic and severe. He or she is then removed from the home and potentially placed in TFCO.

TFCO is intended to be a corrective and supportive learning experience for both youth and their families and uses multiple methods across multiple settings to reinforce and encourage positive behavior. It aims to create opportunities for youth to successfully live with families rather than in institutional settings and to support families in helping to support positive behavioral change through enhanced parenting skills. TFCO's targets are

- (1) a consistent reinforcing environment,
- (2) clear structure and limits with specific consequences delivered neutrally,
- (3) close supervision, and
- (4) avoidance of associations with deviant peers while helping youth develop skills for building positive peer relationships.

TFCO Treatment Model

The TFCO model includes individualized interventions for youth, foster parents, and aftercare placement families; individual and family therapy; and implementation of a behavioral reinforcement program at home and school; as well as case management services and on-call staff support. Throughout the program, youth are reinforced and encouraged for prosocial behavior and continued support is provided for foster and aftercare families. Although TFCO has primarily served youth in the juvenile justice system, it has also served youth in child welfare and mental health populations, children 3 through 17 years of age, and youth in regular state-supported foster care placements. This section highlights the common features of the training model that are implemented across most populations.

Youth

Youth in TFCO participate in a three-level behavior modification program that provides them the opportunity to earn points for meeting treatment expectations at school or at home, such as going to school or doing household chores. Foster parents monitor youth behavior at home and teachers are involved in monitoring attendance, classroom behavior, and homework submission. The system emphasizes positive achievements and unearned points are delivered neutrally. Once youths attain a certain number of points, they move up a level in the system, which earns them access to more privileges, such as participation in community activities. In addition to behavioral reinforcement, youth in TFCO attend individual therapy sessions and weekly sessions with a young adult skills trainer who role models positive attitude and behavior while engaging in prosocial activities with the youth.

Foster Family

TFCO foster families receive extensive support before and during placement. Prior to placement, foster parents receive 12–14 additional hr of training in structuring a home environment with clear expectations and limits. They also participate in weekly group support meetings with other foster parents and have access to 24-hr on-call support from TFCO staff. Additionally, foster parents are called daily, Monday through Friday, to provide information about the youth's behavior and foster parent stress levels to the treatment team.

Parents and Aftercare Families

Meanwhile, the youth's family of origin (or family that he or she will reside with after foster placement) participate in family therapy and parent training while the child is in foster care. Families learn how to implement a behavior management system similar to the one used in the foster home and are trained to provide consistent discipline and encouragement. Therapy prepares families emotionally for their child's return to the home and increases positive relationships within the family. While the child is in TFCO, family sessions and home visits are incorporated for parents to

practice new skills and receive feedback from the treatment team. Although foster placements are typically 6–9 months long, aftercare services are usually sustained for about a year and can remain in place longer at parents' request.

Program Outcomes for Delinquent Youth

This section reviews program outcomes for youth referred to TFCO through the juvenile justice system (ages 12–17 years). Prior to participation in TFCO, youth have typically been involved in multiple treatment efforts, have a history of serious and chronic criminal behavior, and most have experienced multiple incidents of household disruption and failed out-of-home placements. Compared to youth placed in institutional or other group settings, teenagers participating in TFCO show decreased subsequent delinquency, incarceration, and placement disruptions. TFCO is also less expensive than institutional treatment options and has shown sustained effectiveness in reducing recidivism 2 years later.

Gender-Specific Outcomes and Adaptations

Boys

Adolescent boys referred to TFCO typically demonstrate antisocial behavior in early childhood, have social skill and learning deficits, associate with delinquent peers, and have academic failures. Compared to control group participants 1 year following placement, delinquent boys participating in TFCO were incarcerated 60% fewer days and had fewer arrests and significantly less substance use. Two years following placement, boys in TFCO had fewer violent offenses (average of 11 incidents for TFCO group vs. 33 for control group) and were 66% less likely to run away from their programs or homes.

Girls

Although TFCO was originally targeted toward a mostly male population, in the late 1990s and early 2000s, more female adolescents were referred to the system, and adaptations to the intervention were made to meet gender-specific needs. Risk factors for teenage girls referred to TFCO include a history of risky sexual behavior, co-occurring

mental health problems such as anxiety and depression, running away from home, early parenthood/pregnancy, and exposure to childhood maltreatment. To meet the unique needs of girls, the following components were added to the treatment model for females:

- reinforcement and sanctions for coping with and avoiding relational aggression
- emotion regulation skills
- peer relationship-building skills
- strategies to avoid risky sexual experiences and coercion
- educational and incentive-based interventions reinforcing and monitoring abstinence from drug use
- trauma-focused treatment components including relaxation and self-care skills

Teenage girls participating in TFCO have shown significantly better outcomes in a variety of domains when compared to girls placed in group-care settings. When evaluated 1 year following placement, girls in TFCO had fewer days in locked settings, fewer criminal referrals, lower delinquency, and improved homework completion and school attendance. Two years following placement, effects for reduced recidivism and delinquency are maintained, girls are 2.44 times less likely to have become pregnant than girls in group care and also experience reduced depressive and psychotic symptoms. After participating in the TFCO program for 7–9 years, girls show decreased likelihood of engaging in illicit drug use.

TFCO Adaptations

One notable adaptation of the TFCO model is TFCO-P, which focuses specifically on the needs of preschool-aged children (3–6 years old) in the foster care system. Developed in 1996 by Philip Fisher and colleagues, TFCO-P addresses children's behavioral issues, while also focusing on improving foster children's attachment to caregivers, increasing placement permanency, and promoting social skills and school readiness through a therapeutic playgroup component. TFCO-P has been shown to increase secure attachment-related behaviors (e.g., seeking out a caregiver when distressed), decrease placement disruptions

attributed to children's problem behavior, and improve the likelihood that children would remain in permanent placements 2 years later. Because multiple placement disruptions, behavioral issues, and adversity in the home environment during childhood are risk factors for adolescent delinquent behavior and juvenile justice involvement, TFCO-P may be seen as a preventive intervention for youth in the foster care system.

Research on TFCO-P is notable for its attention to underlying explanations for how positive outcomes of the TFCO intervention may be explained at the neurobiological level, particularly with regard to stress-related regulatory processes. Ongoing dysregulation in the stress regulatory neural system might initially prevent neurocognitive and behavioral development from proceeding in spite of a child being in a more responsive and enriched environment. Such dysregulation is common in children in the foster care system and is strongly linked to child neglect, the primary reason children are placed in out-of-home care. Studies measuring cortisol levels (cortisol is a hormone produced by activation within the hypothalamic–pituitary–adrenal axis of the brain and is often used as a measure of experienced stress) of children and foster parents participating in TFCO-P indicate improved stress response patterns as compared to children and foster parents in regular foster care.

Overall, children in the TFCO-P program had cortisol levels similar to children outside of the foster care system, while children in regular foster care showed cortisol patterns indicative of continued dysregulation. Cortisol levels of TFCO-P foster parents dropped immediately after the initial placement and remained low when they were managing children's problem behavior. There was also no association between foster parent stress and cortisol level the next day for children. Finally, researchers found that among children in regular foster care, changes in placement from one foster home to another, or from foster to permanent placement, were associated with diminished and atypical morning cortisol levels. In contrast, among children in TFCO-P, cortisol levels remained stable during placement changes, perhaps due to program components designed to prepare children for transitions. It is also possible that, by providing consistent parenting strategies for all caregivers, the home environment may have remained

more similar before and after placement change for children in TFCO-P.

TREATMENT OF CRIMINAL BEHAVIOR: FAMILY THERAPY

This entry focuses on cost-effective approaches to family interventions related to treating or preventing criminal behavior. Two family therapy approaches with the strongest evidence base for

reducing delinquency are Functional Family Therapy (FFT) and multisystemic therapy. These behaviorally oriented family system approaches teach parenting skills, which has been shown to reduce problem behavior, juvenile recidivism, and adult criminal behavior. These two models have been disseminated fairly widely in the United States, with state and federal funding.

The high cost of training professionals in these approaches and the ongoing expense to ensure treatment fidelity to the training model often make this approach unsustainable over time. Agency staff turnover is often high, requiring training of new staff. Ongoing supervision of trainees tends to improve but does not guarantee positive outcomes. State and federal funding is inconsistent, which makes sustainability problematic.

Because of these issues, Donald A. Gordon focused on developing economically sustainable family interventions with a primary focus on skill training delivered by computers or the Internet. Among the most widely disseminated are the Parenting Wisely (PW) program and the Children in Between (CIB) program. This entry describes the PW program and its theoretical background. Also addressed is how the skills taught by the program are related to reducing criminal behavior. CIB, a parent divorce education program, is discussed with a crime prevention focus.

PW

PW is an interactive parent skill education program for families of children ages 3–18 years that families can access online. A teen version covers ages 12–18 years, and a young child version covers ages 3–12 years. The program is evidence based and reduces risk factors for criminal behavior including child and adolescent behavior problems, child maltreatment, family problems, and risk factors for children being attracted to peers involved in criminal behavior. The program reduces both adolescent and parent substance abuse and family violence including violence between spouses. The program reduces risk factors for teen pregnancy, school dropout, and teen depression and suicide. PW increases protective factors that enhance healthy child development such as increased parent knowledge and use of

effective parenting skills, improved family communication, improved family relationships, and increased support between family members. Research demonstrates PW is effective with culturally diverse, low-income families and families involved with the criminal justice system who were previously resistant to family intervention efforts.

Theoretical Orientation

PW was based on research conducted by Gordon, identifying the most common problems encountered using FFT to treat juveniles involved in criminal behavior. The PW program addresses the same family system concerns and teaches the same skills used in FFT. PW is based on social learning principles, cognitive psychology, family systems theory, mindfulness, and neurobiology. Skills related to social learning principles include clear expectations, contracting, family rules, functional behavioral analysis, nondirective play, planned ignoring, point systems, praise, prompting, role modeling, and social reinforcement through actions such as hugs, kisses, and other forms of positive physical contact.

Content related to family systems theory includes communication skills such as speaking respectfully, active listening, problem-solving, and I-statements. An I-statement is an expression of feelings rather than judgments about another's behavior: For example, "I feel worried when you don't call when you are going to be late coming home." Cognitive content is portrayed in videos by actor voice-overs to depict how family members' thoughts and assumption can contribute to family conflict. The voice-overs portray how positive reframes change the interpretation of behaviors, which helps all family members to see each other in a compassionate, empathic light and to see all family members as victims when conflict occurs. These reframes, along with positive self-talk, help parents to remain calm when responding to conflict. Single parent and step-families' concerns are addressed because these families have a greater risk of child behavior problems. The program provides strategies that go beyond the family unit and target the school system, peer relationships, and substance abuse problems.

The video content of the teen version of PW, developed in 1995, was updated and became available online in 2012. New content on mindfulness and neurobiology was added, which appears to be popular with parents. Research shows mindful parenting increases emotional regulation and improves parental role satisfaction. Neurobiology content portrays how effective or maladaptive parenting affects family members on a neurobiological level and how this either helps or hinders healthy development in children. The video content for the young child version was updated in 2017 and is now available online.

Rational for the Intervention

A common obstacle to intervention for families involved with the criminal justice system is the stigma of attending a parent education class or family therapy. If parents do attend intervention, learning is often impeded by defensiveness and resistance because parents often feel judged and criticized by the parent educator. Before a therapist can begin skill training, a considerable amount of time is spent on developing trust and responding to resistance. This perception of being judged can be eliminated by a computer program, as skill training does not need to be delayed to establish trust. Online PW provides complete anonymity, so learning is not compromised by stigma or defensiveness.

Behavior problems are one of the strongest predictors of negative childhood outcomes such as delinquency, school problems, school dropout, substance abuse, teen pregnancy, mental health problems, suicide, relationship problems, and employment difficulties. PW is a brief, accessible, and cost-effective intervention that has been shown to reduce child behavior problems and does not require intensive practitioner training or expensive ongoing quality assurance mechanisms.

Description of PW

The PW program is easy to use. Parents have indicated that the problem scenarios are realistic and relevant to their families and that the parenting skills depicted are reasonable solutions to those problems. Since PW is interactive, parents cannot complete the program unless they stay

alert and engaged. The program can be used by all agencies that work with children and families such as public health, schools, child maltreatment services, family services, substance abuse agencies, mental health, foster parent agencies, the juvenile justice system, probation services, prisons, and police.

Information is presented in multiple ways—visually, audibly, and in printed text—to increase absorption and retention of information. Parents can proceed at their own pace and usually complete the program in one to three sessions. Parents view video scenes depicting common family conflicts followed by options for how parents can respond that depict harsh or coercive parenting, permissive parenting, or effective parenting skills. Parents chose a response and watch a video depicting the positive or negative consequences of that choice. Each solution is followed by an interactive question and answer critique and a quiz. Viewing the different responses to the problem behavior helps parents realize that child behavior problems can be significantly increased or diminished depending on how parents respond and interact with their children. Each problem scenario is followed by a multiple choice quiz to test learning.

Parents can click on skills highlighted in bold text such as *active listening*, which activates a voice and written text that defines and lists the advantages of that skill. Clicking on a *play examples* button activates a voice providing examples of that skill. Parents receive a workbook that includes critiques to each solution, review questions, and examples of behavior charts. The workbook lists the advantages of each skill, number of steps for performing skills and practice exercises. Parents' progress on program completion, review questions and the multiple choice tests and online skill practice is tracked automatically. Parents are prompted to complete unfinished portions and to complete skill practice exercises through e-mails or cell phone text messages.

The adolescent program covers 10 problem scenarios that are common in many families but occur even more frequently in high-risk families. These include the following: getting children to do housework; helping children with school problems; curfew problems; step-parent step-child conflict; monitoring school, homework, and

friends; loud music and incomplete chores; speaking respectfully and sharing computer time; sibling conflict and aggression; getting children ready for school on time; and finding drugs in a teen's bedroom. The young child program problem scenarios include the following: children acting up in public, helping children with poor marks and school troubles, children interrupting conversations and phone calls, helping children solve conflict with their friends, helping children get to bed on time, helping children get ready for school, and controlling sibling arguing.

PW has been shown to be helpful when a family's access to intervention is problematic or unlikely, or when parents are likely to be resistant to traditional parent interventions. The program can be used on a continuum for either prevention or treatment. It has been used in combination with FFT and has resulted in more rapid learning of family communication skills and fewer FFT sessions.

The program has been implemented across the United States, as well as in Australia, Canada, China, France, Ireland, New Zealand, Portugal, Singapore, and the United Kingdom. There are English and Spanish versions of the program and an Italian version is being developed. The families depicted include African American, Hispanic-Latino, and Caucasian. The program has been shown to be effective with culturally diverse populations. PW is included in the National Registry of Evidence-based Programs and Practices based on the quality of research support and the ease of successful dissemination.

CIB

Gordon also developed an interactive parent education program called *CIB*, formerly called *Children in the Middle*, which can be accessed online or used with in-person classes in most U.S. states. This program helps prevent criminal behavior and related problems in families disrupted by divorce or separation. Behavior problems and school dropout occur frequently with these children and they are substantially more likely to become delinquent. This risk is primarily mediated by parental conflict and fathers dropping out of their children's lives. The *CIB* program teaches parents to communicate respectfully, regulate their emotions,

and protect their children from conflict. This evidence-based program has been shown to reduce parental conflict, improve communication, reduce relitigation, and help both parents stay involved in their children's lives. Therapists can access the program online as an adjunct to treatment done in the home. *CIB* is a more affordable, accessible alternative to the highly variable approaches of marital and family therapists and to the evidence-based family therapy interventions discussed earlier. The low cost of the program is easily absorbed by many parents so the program can be recommended by agencies or therapists with no need to access limited state or federal funding.

TREATMENT OF CRIMINAL BEHAVIOR: GROUP PSYCHOTHERAPY

It is commonly recognized in criminal justice and correctional circles that treatment with offender populations is superior to punishment alone. Many therapeutic programs have proven effective, including psychotherapy for the treatment of

psychopathology and distress, and contribute to offender rehabilitation. As in the free world, psychotherapy in corrections (including jail, prisons, and community corrections) is conducted individually or in groups. Individual psychotherapy consists of one-to-one interactions between a psychotherapist and client, whereas group psychotherapy consists of a small group of at least three or more individuals (though, usually about eight clients), with a therapist or co-therapists.

Individual and group psychotherapy has proven effective for both rehabilitation and basic mental health services. Rehabilitation-oriented psychotherapy aims to prepare incarcerated offenders for community reentry or to enhance the community success for offenders treated in community corrections, such as probation or parole. Basic psychotherapy services aim to stabilize offenders with mental illness and general mental health concerns. Basic psychotherapy services target psychiatric disorders (e.g., depression, anxiety, post-traumatic stress disorder, sleep disorders), personality disorders, and general mental health concerns (e.g., anger management, self-esteem problems). Basic psychotherapy services also assist offenders with general transitional issues, such as adjusting to incarceration, relationship problems, and inmates' end-of-life issues, to name just a few examples. To date there is no evidence that individual or group psychotherapy has proven more or less effective than its counterpart for treating these myriad of issues. This entry discusses the advantages of group psychotherapy relative to individual psychotherapy and the effectiveness of group psychotherapy with criminal justice populations.

Advantages of Group Psychotherapy

Group psychotherapy offers two distinct advantages over individual psychotherapy. First and foremost is the fiscal advantage group psychotherapy offers compared to individual psychotherapy. Specifically, group psychotherapy offers an economical advantage as it allows service providers to reach a greater number of offenders than individual (one-to-one) modalities allow, at little to no additional cost. For example, 1 hr of group psychotherapy allows a therapist to treat, on average, 8–10 offenders, instead of only one offender in the same individual psychotherapy hour.

As a result of the economical benefit, group psychotherapy in corrections experienced a rapid growth in the 1950s, such that by the 1960s groups became the treatment modality of choice. Importantly, most correctional and criminal justice interventions and treatment targets (e.g., treatment programming aimed at reducing criminal thinking and associations with criminal others, depression and anxiety treatment protocols, and efforts at improving institutional adjustment and community success) can be modified for group delivery.

Group psychotherapy has an added benefit of multiple interpersonal interactions that individual psychotherapy is unable to offer. That is, in individual psychotherapy, the only relationship is that between the therapist and client, whereas in group psychotherapy there are several individuals, each with their own interpersonal style and presenting issues. Group psychotherapy offers the opportunity to utilize the group interactions to facilitate personal growth and behavior change. In fact, one of the primary benefits of group psychotherapy in corrections is that inmates learn to develop functional prosocial peer relationships. Further, the psychotherapy group offers a social support network that may help offenders cope with the myriad of issues and difficulties encountered when navigating correctional systems (e.g., transitioning to jail and prison) or when complying with the conditions of probation or parole.

Of particular benefit for an offender population may be a group psychotherapy approach developed by Irvin Yalom and known as the *interpersonal process-oriented approach to group psychotherapy*. In this approach, therapists help offenders maintain a focus on the interactional patterns of individual group members to work on problems in the *here-and-now*. In other words, offenders engage in behavioral change by working through problems they have in real time, as experienced, with other group members. For many offenders, this is the first opportunity they have had to work through interpersonal problems with others in a safe and constructive manner. Such opportunities afford offenders a chance to voice frustrations, hurt feelings, anger, and more in a productive manner to improve relationships and break the cycle of dysfunctional communication that often permeates their interpersonal

relationships. Individual psychotherapy, consisting of one-to-one interactions, does not afford this in vivo (in real-time) experience.

Effectiveness of Group Psychotherapy

Given issues of overcrowding in modern correctional systems, it is also important to consider issues beyond efficiency, specifically with wasted resources such as ineffective therapeutic efforts. That is, consideration must extend beyond efficiency to consider the efficacy of efficient resource utilization. Simply stated, group psychotherapy is an effective treatment modality with offenders.

It is important that group psychotherapists perceive their work to be effective at producing positive treatment outcomes. More importantly, however, group psychotherapy treatment outcome evaluations have provided more definitive positive outcomes. Specifically, evaluation and treatment outcome studies have shown that group psychotherapy is effective across a variety of outcomes, including in improving institutional behavior (e.g., reduced disciplinary infractions and improved work performance ratings). Group psychotherapy has shown to be effective at improving general psychological functioning (e.g., self-actualization, enhanced empathy, and locus of control) and reducing symptoms associated with personality disorders. Group psychotherapy has also shown to be effective for reducing problems such as anger, stress, anxiety, and depression.

Possibly of greatest importance is that group psychotherapy has been shown in research to result in improved community reentry (e.g., reduced recidivism and improved parole outcomes) as well as more favorable attitudes toward rehabilitation programs. When research studies were considered collectively in a meta-analysis, results indicated positive group psychotherapy treatment effects across a range of outcome variables, including institutional adjustment, anger, mood states, interpersonal functioning, and psychological functioning.

Despite the efficiency (and financial benefits) of group therapy, however, most mental health professionals in corrections continue to prefer individual psychotherapeutic services over group psychotherapy services. Unsurprisingly given privacy and confidentiality concerns, offenders

overwhelmingly prefer individual psychotherapy over group psychotherapy. Nevertheless, research has shown that mental health professionals working in correctional systems appear to spend about the same amount of time providing individual and group psychotherapy services.

Comparing Group and Individual Psychotherapy

Individual and group psychotherapy services are effective with offender populations and for dealing with the myriad of problems encountered in corrections. Although there appears to be no distinction between individual and group modalities with regard to effectiveness, group psychotherapy is much more economically advantageous. It is an effective modality for facilitating the development of everyday prosocial skills, such as anger management, stress management, and problem-solving skills, as well as for treating problem specific groups (e.g., offenders with substance abuse issues) and criminal risk factors (e.g., criminal thinking and criminal associates). Finally, group psychotherapy is also effective for reducing the risk of sex offending and other types of criminal recidivism, as well as for preparing offenders for community reentry.

TREATMENT OF CRIMINAL BEHAVIOR: SUBSTANCE ABUSE COUNSELING

Substance use disorders refer to the harmful or hazardous use of psychoactive substances including alcohol and drugs. Treatment interventions address the biological, psychological, and social factors that contribute to substance use disorders. The association between substance use and crime is well established in the empirical literature. Substance users can become involved in the criminal justice system through (a) possession of an illicit substance, (b) sale or illegal distribution of a substance, or (c) engaging in other illegal activity, such as theft, to support continued drug use.

Substance use disorders are chronic and relapsing and are prevalent within the criminal justice system. The need for coordination between the criminal justice system and substance use treatment is critical for reducing recidivism and increasing quality of life outcomes. This entry focuses on substance use and counseling within the criminal justice system. Background on the history and need for substance abuse counseling within the criminal justice system, evidence-based interventions in criminal justice settings, and selected clinical issues are highlighted.

History of Counseling in Criminal Justice

Substance abuse was classified in the 1930s as a medical problem when two federal facilities were opened in Lexington, KY, and Fort Worth, TX. Through the legislative efforts of the Federal Bureau of Prisons, these facilities were established by the U.S. Public Health Service to provide treatment for federal prisoners and substance abusers.

Based on the observation of high relapse rates from these facilities and modeled after the California and New York state narcotic addict civil commitment programs, the federal Narcotic Addict Rehabilitation Act was passed in 1966. This federal civil commitment program provided community aftercare treatment following discharge from the Lexington and Fort Worth facilities. Later, treatment facilities were opened across the United States. Many of these community treatment programs provided the foundation for urban community-based substance abuse counseling and treatment.

Another milestone linking criminal justice and substance abuse treatment, now referred to as *reentry* and *continuity of care*, is the Treatment Accountability for Safer Communities (TASC) program. TASC is a diversion and case management program designed to link community corrections with drug abuse treatment. TASC provides identification, assessment, referral, case management, and monitoring services for substance-dependent offenders of nonviolent crimes. TASC reduces drug use and keeps drug abusers in treatment longer.

Prevalence of Substance Use

Substance use among U.S. criminal justice populations is 5 times higher than in the general population. Over three quarters of incarcerated individuals report substance use in their lifetime and more than half meet diagnostic criteria for a substance use disorder. Rates of use vary by substance, with alcohol the most commonly used substance. Other substance use varies by demographic group and availability, with marijuana, psychotherapeutics (e.g., nonmedical prescription opioid use), and cocaine representing the most frequently used substances in the United States.

Substance Abuse Intervention Through the Criminal Justice System

Substance abuse interventions in criminal justice settings can be effective if well delivered and targeted. Overall, offender substance abuse treatment has been described as (a) civil commitment (i.e., supervision of parolees with urine testing and counseling), (b) criminal justice authority

(i.e., community corrections), (c) offender community treatment services (i.e., community substance abuse treatment), and (d) treatment services in prisons and jails. Intervention options can range from intensive counseling, as well as behavioral and pharmacological treatment, drug court, drug urine testing, self-help groups such as Alcoholics Anonymous and Narcotics Anonymous, relapse prevention, and supervision on probation and/or parole.

Substance Abuse Counseling and Interventions

Substance abuse counseling and interventions may need to begin with detoxification. Detoxification refers to the removal of substances from the body while monitoring and managing the symptoms of withdrawal. Withdrawal syndromes vary by drug class, severity of use, and number of substances misused. Detoxification can be either medical with medication for withdrawal or social detoxification without medication, depending on withdrawal-related medical complications. Because detoxification is brief and with limited success alone, justice involved clients, like others, usually require treatment including counseling. However, substance use education and awareness are the most common substance-related services in corrections.

The therapeutic community is a traditional treatment modality with successful outcomes over time. Therapeutic communities acknowledge that substance use is part of a large, complex behavior disorder and incorporates a community approach of mutual self-help focusing on behavior change over a long period of time, which usually includes counseling. For incarcerated individuals, in-prison therapeutic communities with dedicated housing address treatment needs. The effectiveness of prison-based counseling can be reduced if it is not linked to community reentry follow-up and aftercare, counseling, and recovery resources. For those transitioning to community care, therapeutic communities can provide transitional living including continued substance abuse treatment and employment to decrease recidivism. Reentry halfway houses are less structured than therapeutic communities and can serve as a transition between prison and independent living. However, the point

of transition from incarceration to community reentry is a high-risk time and successful reentry is limited because a mechanism for exchanging and sharing assessment information by prison-based treatment programs, parole officers, and community-based treatment programs at community reentry is not generally available.

Community and other transitional programs as well as aftercare programs can provide support during this time. The 12-Step model, including Alcoholics Anonymous and Narcotics Anonymous, is grounded in a chronic framework as an intervention and relapse prevention program. The 12-Step model is a member-driven program based on the collective experience of recovering individuals from substances. The 12-Step meetings can be attended during incarceration and at discharge reentry. Major advantages of mutual help groups such as the 12-Step approach are accessibility and free of charge. In addition, meetings can be attended when risk of relapse is high and counseling resources are not available. Consistent attendance at 12-Step meetings is associated with decreases in substance use.

The combination of counseling and pharmacotherapy is often more effective than either counseling or pharmacotherapy alone. Pharmacotherapy or medication-assisted therapy approaches utilize prescribed medications for detoxification, reducing drug craving, and maintaining abstinence. Opioid replacement therapy for heroin and opioids (e.g., methadone, buprenorphine) is the most commonly used pharmacotherapy. Medications that block the effect of an abused substance (e.g., naltrexone for opioids or alcohol) or produce an aversive reaction if the abused substance is taken (e.g., disulfiram for alcohol) can also be effective. Medication compliance, however, is key but often minimal. As of 2016, there are no approved pharmacotherapies for stimulant use disorders (i.e., cocaine or methamphetamine), although naltrexone and *d*-amphetamine have shown promise.

Drug court (also called *drug treatment court*) is centered on individual and group counseling with links to addiction treatment and the criminal justice system. The drug court model, like diversion programs, is designed in part to alleviate prison and jail overcrowding, is a cost-effective approach to decrease substance use and divert nonviolent

substance users from incarceration. Drug court and probation-based substance use treatment programs use judicial authority from the courts to enhance community continuing care for substance-involved offenders. The integration of counseling and treatment services in justice system processing has supported a nonadversarial judicial interaction among judge, prosecutor, defense attorney, and counseling staff. Drug court also utilizes frequent drug testing to monitor abstinence and often requires participant employment. A major benefit is that drug courts are able to respond quickly to substance use relapse since the court retains direct jurisdiction over clients.

Substance Abuse Counseling and Women

Women in the criminal justice system require gender-specific counseling and other services to address special issues including mental health, victimization and violence, relationship issues, children, and physical health that are compounded by substance use disorders. Substance abuse counseling for women should address each of these domains and facilitate linkages with reentry community treatment. For example, interventions targeting behavioral health risks including sex exchange for drugs, sex with multiple partners, inconsistent condom use, and risky sex can also improve substance use outcomes. Barriers to substance abuse treatment for women, including stigma, limited or no partner or family support, lack of childcare, pregnancy, child custody issues, and co-occurring mental health. In addition, among U.S. women prisoners, it has been estimated that over one third of women report intimate partner abuse and nearly three fourths report being beaten by a partner. As such, trauma-focused interventions are important for women substance users.

Final Thoughts

Substance use disorders are chronic and relapsing and highly prevalent in criminal justice settings. Coordination between the criminal justice system and substance use counseling and treatment can decrease recidivism and improve quality of life outcomes. Substance abuse interventions in criminal justice settings can be effective if

evidence-based, well delivered, and targeted. Effective interventions incorporate the interaction of brain, behavior, and environment, which can be used as a framework for criminal justice counselors. Thus, effective interventions integrate multiple approaches including individual and group counseling, behavioral therapy, continued care following the intervention, education, drug court, and specialized clinical services for populations like women.

TREATMENT OR PROGRAM OUTCOME EVALUATIONS

Large sums of public money are spent on offender rehabilitation programs every year. However, many offender rehabilitation programs are not effective in reducing reoffending. Strong conclusions can be drawn about the effectiveness and quality of a correctional treatment program when a rigorous evaluation is conducted. A sound evaluation is one that is likely to be replicable (i.e., someone else should be able to conduct the same evaluation of the program and obtain the same results). Since policy makers and criminal justice administrators are being held accountable for the outcomes of these correctional treatment programs and the money invested in them, these officials rely on evaluations to help them make more informed decisions about the continued funding of these programs. This entry focuses on how evaluations of correctional treatment programs are conducted and what constitutes an ideal or optimal evaluation.

Importance of Program Evaluations

Policy makers and criminal justice administrators do not wish to waste valuable resources on programs that do not work. Given the sums of taxpayer money spent on these programs, the general public also demands that these programs be effective. Evaluations provide these stakeholders with key information about these programs and allow informed decisions to be made.

Evaluation research should be considered a tool for improving program effectiveness. It provides feedback and monitoring of program performance and contributes to the knowledge base regarding effective programs. Evaluations assist in identifying the particular shortcomings of programs that need to be addressed.

In order to know whether offender rehabilitation programs are truly effective, rigorous formal evaluations of these programs are required. This allows researchers to draw firm conclusions about the impact of correctional programs on recidivism. Anecdotal information and informal evaluations are generally not considered to be as informative and acceptable.

The failure to evaluate programs often means offenders are provided with ineffective programs. When these programs fail, offender rehabilitation in general comes to be viewed as impossible. Moreover, offenders are not provided with programs which would have been successful. It also discourages the development of effective programs.

How Evaluations Are Conducted

Evaluations should not be considered an afterthought. They should be part of the everyday operations of programs. Programs should be designed with evaluation in mind, and data should be collected on an ongoing basis. If possible, the evaluator should help set up an automated database to collect this information in order to make these periodic evaluations easier to conduct.

One of the first stages in the evaluation process is determining who will actually conduct the evaluation of the correctional treatment program. Ideally, the developer of the program should not be the evaluator of the same program. An independent evaluation conducted by an individual/group will help reduce bias and provide more credibility to the evaluation. Program developers have an inherent interest in demonstrating that the programs that they developed are successful and help reduce reoffending.

Optimally, the evaluation should be planned prior to treatment program delivery. These are referred to as *prospective evaluations* and are carried out simultaneously with program participation. The evaluator is involved in the design of the study from the beginning. This type of planning allows for the development of the selection criteria for participants, the identification of appropriate measures to assess study participants, the assignment of clients to groups, and how often and when they will be measured. Furthermore, pre-planning allows for the development of treatment

protocols such as who will deliver the treatment, when, where, over what period of time, and with what dosage. Retrospective (i.e., after the fact) evaluations are typically considered methodologically weaker.

Research Design

A definitive statement about the effects of specific treatment programs for offenders cannot be made without the inclusion of a comparison group that was not provided with the program. Ideally, clients should be randomly assigned to *treatment* and *control* groups in order to guard against any potential source of bias in group assignment. If random assignment is impossible or not practical, a quasi-experimental design should be employed to provide a reasonable standard against which to assess treatment effects. In a quasi-experiment, the treatment and control groups are matched on important characteristics that are related to outcome. Evaluations should include detailed accounts of the comparison groups.

Offender attrition is another source of bias in evaluating treatment effectiveness. High dropout rates tend to positively bias outcome evaluations. Program completers represent a positive selection of clients, whereas dropouts often have much higher recidivism rates. Results should be presented separately for the different groups (i.e., treatment, treatment dropouts, control, and control dropouts). Researchers must keep track of dropouts and treatment failures in their evaluation of correctional treatment in order to understand the true treatment effects. Improvements to the program may also need to be made in order to increase retention and reduce dropouts.

Program Outcomes

Criminal justice officials are primarily interested in recidivism as an outcome measure in program evaluation. Wherever possible, multiple indicators of recidivism should be used. For example, arrests, convictions, incarceration rates, type and severity of offences, and technical violations could be examined. Examining arrests without follow-up to determine if the offender is convicted may provide a limited representation of the outcome following treatment completion. In terms of arrest,

evaluators could also examine time until arrest. This measure would provide an indication if the program was successful in delaying reoffending. There is also a need to conduct follow-up studies of sufficient length to adequately assess recidivism (e.g., 3 years). Shorter periods may not be sufficient to determine the true effects of the program on the offender.

Intermediate measures should also be incorporated into the design. For example, measures of attitudes (e.g., antisocial attitudes), personality, cognitive skills (e.g., social problem-solving), and correctional institutional adaptation could be included. Others may include changes in drug and alcohol use severity, educational achievements such as finishing high school, and employment achievements such as days employed. Some intervening behaviors (e.g., social problem-solving skills) must be modified in order for changes in criminal behavior to occur or be observed. Therefore, it is important that program officials include reliable and valid measures to assess these intervening behaviors or intermediate targets. Attempts should be made to use standardized instruments in order to provide accurate assessments and to allow for comparisons across evaluations.

Furthermore, the sample should be of sufficient size to enable differential effects to be examined (e.g., for which offenders does the program work best for and in which types of contexts does it work best). No program works equally well for all offenders. The characteristics of each offender such as gender, race, ethnicity, and age should be recorded and incorporated into the analysis. In addition, the learning styles of offenders, their personality characteristics, and their motivation for treatment should be assessed and recorded. These data allow the opportunity to assess differential program effects. For example, a particular program may work best for offenders between the ages of 30 and 40 years but not between the ages of 20 and 25 years. Or a program may be more effective for female offenders with certain personality characteristics compared to others.

Program Quality

Outcome studies focus on recidivism results and provide a measure of the outcome of programs. However, they do not offer a complete

representation of what happened during the program. These studies do not provide much information about why a program works or does not work. Combining outcome indicators with assessments of program quality can provide a better indication of an intervention's effectiveness. In order to understand why a program works or does not work, efforts need to be made to get inside the *black box* of an intervention program. This would provide information on what these programs do and how they do it. Evaluations can provide an assessment of the soundness of the theoretical model underlying the treatment program approach and its conceptualization. In addition, they measure implementation and integrity. Program implementation must be carefully monitored to ensure that the program is delivered in a manner consistent with the original protocol. These questions need to be asked and answered as part of the evaluation process: How many sessions were actually delivered? How long were the sessions and over what period of time? How many sessions did program participants attend? Was the dosage appropriate to the risk level (i.e., the offender's risk of reoffending)? In addition, issues pertaining to program staff characteristics, training, and supervision need to be examined. Evaluations should assess the personality characteristics and educational backgrounds of staff, document the amount of and type of training that staff received, and document the amount and type of supervision they received.

Data may be collected on the quality of the program by interviewing program administrators, treatment personnel, and treatment participants. The interviews with treatment participants may take the form of client satisfaction surveys or exit interviews. The evaluator may also collect data from observation of treatment group sessions and services. Other sources of information include treatment materials, manuals, and curricula, and a review of a sample of offender case files.

Benefit–Cost Analysis

When correctional treatment programs are delivered as designed, the programs are more likely to produce positive returns on investment. Evaluations should also measure the economics of each

program to determine whether the benefits outweigh the costs. This analysis would assist in determining whether taxpayer dollars invested in the programs would save money in the future. In other words, it needs to be determined whether there is a positive return on taxpayer investment. In these analyses, attempts are made to calculate the cost of the particular program per participant compared to the cost of the alternative (i.e., no treatment or treatment as usual).

Given the fiscal constraints imposed on them, criminal justice administrators are increasingly called upon to show that effective programs have also produced a monetary gain (e.g., for government) or cost less than other forms of intervention.

TRIALS, CRIMINAL

The criminal trial is a formal process that is governed by the rules of criminal law, procedure, and evidence. Each jurisdiction in the United States has its own criminal trial procedure. However, criminal trials generally follow a similar process—one that is reflective of the adversarial nature of the court system, in which the defendant is confronted by and faces the state as the opposing authoritative body. Unlike what is portrayed on many television shows such as *Law and Order* and *How to Get Away with Murder*—whereby an attorney intentionally puts his or her client on the stand knowing full well that the client may lie, or whereby witnesses are asked leading and prejudicial questions and outbursts of victims or angered loved ones fill the courtroom—the modern-day criminal trial is often a technical affair. It is governed by an adversarial proceeding in which both the prosecution and the defense must follow a set of procedures. The objective is to have each side present its case in its most favorable light. Although there may be individual victims involved in criminal cases, the trial itself is not brought forth by them but by the state (or federal government). All crimes are classified as offenses against the state (society), and as a result, a representative of the state—the prosecutor—is responsible for filing and pursuing the case in criminal court. A defendant can choose the trial to be heard before a jury or a judge.

Waiver

Although most criminal trials are heard and decided by a jury, some defendants waive their constitutional right to a jury trial and opt, instead, for a bench trial. A bench trial is when a judge is responsible to hear the criminal matter, instead of an impartial jury, a right afforded by the Sixth Amendment to the U.S. Constitution. There are many different reasons as to why a defendant may waive his or her right to a jury trial. For example, a defendant may want to put his or her fate into only one person's hands, the judge, instead of several, which would occur with a jury. In addition, the defendant may feel as though the judge may be more sympathetic or be able to assist better with cases that are complicated by factual

circumstances. Lastly, bench trials tend to be less time consuming and costly. Even though one has a right to waive one's right to a jury trial, it is not always granted. A judge can veto the waiver at the request of a prosecutor and therefore require a jury trial if he or she feels a fairer trial will result.

History of the Jury Trial

The use of juries in a criminal trial can be traced to the 12th century. In the English common law system, the county sheriff was charged with selecting the members of the jury. Perhaps unsurprisingly, the sheriff would typically choose jury members who held views and positions favorable to the reigning monarchy—and reach verdicts accordingly. If the jury members did not reach a favorable decision—or one at all—the sheriff had the authority to withhold food from and even punish the jury members in order to prevent them from siding with the defendant which, ultimately, was against the monarchy. A jury's decision was deemed incorrect if, when tried by a jury of Knights, an opposite verdict was reached. The use of juries to decide guilt in a criminal trial became commonplace in England by the mid-1200s. Later, this practice was adopted by American colonists. However, juries were originally used as a means to rally against British laws, and their use was later included as a right within the U.S. Constitution. Although the right to a jury trial has been recognized since the signing of the U.S. Constitution in federal courts, it was not extended to the states until 1968 in the case *Duncan v. Louisiana*.

The Sixth Amendment grants the right to a jury trial in *all criminal prosecutions*. However, the Supreme Court has narrowed this right in the case of *Baldwin v. New York* (1970), stating that the accused only has a right to a jury trial if the imposing sentence would equate to 6 months or more of confinement in prison, regardless of whether the crime was a felony or a misdemeanor. For anything fewer than 6 months, the accused is not entitled to a jury trial unless deemed otherwise, typically by a state statute.

History of a Bench Trial

The bench trial originated during the 17th century in the American colonies. However, it was not

until the 19th century that bench trials became a more common practice in several states. Bench trials are more common in the lower criminal courts. In a bench trial, the judge has sole authority in hearing evidence and reaching a verdict. He or she is the trier of the law and the trier of the fact. What this means is that a judge will decide on the issues of the law and also decide whether the defendant should be found guilty, which would otherwise be the responsibility of the jury. Aside from finding the defendant guilty, a judge has several administrative decisions that he or she must make. The more common administrative decisions include dismissal of the case, granting of motions, maintaining courtroom conduct, and the determination of guilt or innocence.

Two prominent cases concerning the right to a bench trial is *Patton v. United States* (1930) and *United States v. Jackson* (1968). In *Patton v. United States*, the defendants argued in a federal criminal trial that an individual cannot waive his or her right to a jury trial because defendants lacked the authority to waive this right. However, the Supreme Court stated that the right to a jury trial can be waived in federal criminal cases at the request of a defendant, as long as the presiding judge and government attorneys agree to the waiver and the consent be *express and intelligent*. *United States v. Jackson* enhances the requirement stating that the waiver be voluntary, to limit the possibility of government coercion.

Charging the Defendant

Once a defendant is charged with a crime, depending on the state, the process varies as to whether charges will be heard before a grand jury or a preliminary hearing. The grand jury was created as a means to protect against a possible arbitrary prosecution, where a judge might be a puppet of the government. This was an early development of English common law and later incorporated into the Fifth Amendment to the U.S. Constitution. The grand jury acts as the community's conscience, determining whether the prosecution has justified the need of a trial, based on evidence and the testimony of witnesses. This is a closed hearing, meaning that the defense attorney, the defendant, and the public are not allowed to attend. The grand jury is tasked with determining whether

probable cause exists for the prosecution. If probable cause exists, an indictment, also known as a *true bill*, is affirmed and charges are brought forth.

The second state process, a preliminary hearing, which is used in about half of the states, is when a prosecutor provides a written accusation specifying that a particular individual committed a certain offense. This written accusation is called *information*. When this mechanism is chosen, a preliminary hearing is required. The preliminary hearing has the same purpose of the grand jury hearing. However, the preliminary hearing provides some advantages for the defendant. For example, the preliminary hearing provides the defense notice of what evidence the prosecution has concerning the case. It is during this phase that a judge may dismiss the charges. Other unique aspects of the preliminary hearing include the defendant's right to challenge the prosecutor's evidence and to cross-examine the state's witnesses. It is also during this time that a defendant can choose to waive his or her right to a criminal proceeding. A waiver may be chosen to speed up the criminal justice process by pleading guilty, or it may be used to avoid any negative publicity that may occur if a criminal proceeding were to take place. A waiver prevents the prosecutor from having to reveal the state's evidence. In the end, either the grand jury or a preliminary hearing establish whether probable cause is sufficient to merit a criminal trial.

The Plea

After this hearing, an arraignment takes place before the court. This is where the case will be heard. During this time, the presiding judge informs the defendant of the charges, which is a constitutional right granted by the Sixth Amendment. Counsel is also appointed if needed. It is during this phase that a defendant is asked to enter a plea. There are four plea options: not guilty, not guilty by reason of insanity, guilty, or *nolo contendere* (*no contest*). A trial date is set if the defendant enters a plea of not guilty or not guilty by reason of insanity. A date for sentencing is arranged when the defendant pleads guilty or *nolo contendere*. A plea of *nolo contendere* states that the defendant does not deny or accept

responsibility for the crimes charged but agrees to accept the punishment afforded by the court. Essentially, it is a plea of guilty, but it cannot be used as proof in subsequent legal matters, for example, a civil lawsuit or appeal, since there was no admission of guilt.

Trial Process

The criminal trial begins with a venire—this is a group of individuals that are called in for potential jury duty. Next is the *voir dire*, which is the process used to produce an unbiased and objective jury that reduces the larger group of jurors to a smaller panel of jurors, based on their responses from various questions asked by both the prosecution and the defense. After jury selection, the prosecution begins with an opening statement to the jury. Here, the prosecutor states the criminal charges, outlines the facts concerning the case, and describes how the state will prove the defendant's guilt beyond a reasonable doubt. Next, the defense begins with its opening statement, indicating how the accused is not guilty. The prosecutor then presents evidence through a direct examination of its witnesses. These witnesses can include eyewitness accounts of the incidents, expert witnesses, police officers, and victim statements. During the direct examination, the prosecution questions each witness to further show guilt of the accused.

After questioning by the prosecution, the defense conducts a cross-examination of the state's witnesses. The goal of the defense team is to challenge the accuracy and/or credibility of the state's witnesses. Next, the defense has the option of presenting witnesses to refute the government's allegations. It is also during this time that the defense attorney decides whether to have the defendant testify. The defendant is protected by the Fifth Amendment to the U.S. Constitution, which holds the right to be free from self-incrimination. Therefore, a person cannot be forced to testify against him- or herself. Once the defense is finished, the prosecution may rebut what the defense presented. At the end of the state's rebuttal, the defense may be granted a sur-rebuttal—only responding to the prosecution's rebuttal. During rebuttals, no new evidence can be introduced. After, the closing arguments begin with the defense and end with the prosecution.

The facts are reviewed and presented in a favorable manner for each side (i.e., defense and prosecution). Next, the judge instructs the jury on the law, evidence, and standards of proof needed to convict. Then, the jury deliberates on a verdict. Once a verdict is rendered, this is usually read to the judge and sentencing is imposed.

Trial Rights

While some of the administrative and judicial processes differ based on jurisdiction, the majority of them can be found at similar stages of the criminal trial process, providing similar rights—specifically to the accused. Many of the rights that govern the criminal trial process are guaranteed by the Sixth Amendment to the U.S. Constitution:

In all criminal prosecutions, the accused shall enjoy the right to a speedy and public trial, by an impartial jury of the state and district wherein the crime shall have been committed, which district shall have been previously ascertained by law, and to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining witnesses in his favor, and to have the assistance of counsel for his defense.

Speedy Trial

Though vague as proscribed in the U.S. Constitution, the right to a speedy trial has been addressed by legislation such as the Speedy Trial Act of 1974. There are a host of standard procedures, as well as tactics by the defense attorney, that may extend or delay the commencement of a criminal trial. Pretrial motions, plea negotiations, inefficient scheduling, the granting of continuances, and even abuse of time by court personnel have made what constitutes a violation of the speedy trial guarantee. As a result, academics and practitioners alike have put forth suggestions for improving the efficiency of the criminal trial process.

Public Trial

For a criminal trial to meet the constitutional guarantee of being *public*, it must be open to the

public. Only in rare instances is this right limited, allowing anyone who wants to see a criminal trial the ability to do so. However, in some cases certain items of evidence are not open for public view for the protection of the victim. The right to a public trial does not necessitate that members of the public are present during trial, just that there is the ability for them to do so. Similarly, not all persons interested in viewing a criminal trial are guaranteed the ability to do so. A judge may limit viewership of a criminal trial due to capacity limitations as well as—due to ejection—the removal of any disruptive member of the viewing public.

Impartial Judge

Although not stated explicitly in the U.S. Constitution, every defendant in a criminal trial is afforded the right for his or her trial to be presided over by an impartial judge. Not until *Tumey v. Ohio* (1927) did the U.S. Supreme Court rule on this issue, holding it to be a violation when a judge “has a direct, personal, substantial pecuniary interest in reaching a conclusion” in a case. Impartiality is paramount to just the application of the law in a criminal trial. Judges are in charge of determining what evidence is allowed into the courtroom, providing the jury with legal definitions and instructions about the law or laws in question, and sentencing when applicable.

Right to an Impartial Jury

The Framers of the U.S. Constitution highlight the importance of the right to an impartial jury in criminal cases by mentioning the right in both the original Constitution (Article III, Section 2) and in the Bill of Rights (the Sixth Amendment). In all criminal prosecutions, the accused has a right to an impartial jury of his or her peers. The duty of the jury is to hear cases without prejudice and to deliver an unbiased verdict.

Right to Counsel at Trial

The defendant has a right to counsel at various points in the justice process. Based on the Supreme Court case *Scott v. Illinois* (1979), during a state criminal trial, an indigent defendant who is facing the possibility of incarceration must be provided

counsel. This possibility includes cases where the defendant is sentenced to probation in which a jail or prison term or any other sentence that contains the threat of a future incarceration is suspended.

Right to Be Competent at Trial

Defendants who are criminally charged must be deemed mentally competent in order to stand trial. Competency to stand trial is rooted in the English common law prohibition against trials in absentia. This absence refers to the right that defendants have to being physically and mentally present at their trial. Jurisdictions vary with their requirements for determining competency as well as the burden of proof in proving such in a criminal case. Some states, for example, require defendants only to understand the nature of their wrongdoing, while others offer the alternative of a defendant having willful control over his or her behavior.

Right to Confront Witnesses

The framers of the Constitution argued that in order to have a fair trial, the defendant should have a right to see and cross-examine all witnesses. The reasoning was based on the idea that individuals would have a harder time lying when the person is in front of them. Thus, only truthful evidence would be presented. It is the Sixth Amendment that affords the defendant the right to confront the state's witnesses, stating that "In all criminal prosecutions, the accused shall enjoy the right . . . to be confronted with the witnesses against him." Thus, this Amendment grants the defendant the right to participate in his or her trial by being present to make sure hearsay, or second-hand, evidence is not entered in as evidence. Only firsthand knowledge is permissible.

Right to Compulsory Process

The accused, as a result of the Six Amendment, has a right to have a compulsory process—meaning that he or she has a right to obtain witnesses in his or her favor. This can be done via a subpoena, which is an order that requires a witness on a specified date and place to appear in court. This fundamental right was decided by the

Supreme Court in the case of *Washington v. Texas* (1967).

Right to Be Convicted Beyond a Reasonable Doubt

The standard of proof needed for a defendant to be convicted in a criminal trial at the adjudicatory stage is proof beyond a reasonable doubt. This is the highest standard of proof that prosecution must overcome. The reasonable doubt standard is essential since the U.S. system is based on the presumption of being innocent until proven guilty. This standard helps prevent the innocent from being convicted.

The Appeal

Once the defendant is found guilty, the defense may begin to petition the courts for an appeal. An appeal is when the defense petitions the appellate court to review the procedures used during trial, claiming basis or error affected the conviction in the trial court. The appellate court reviews a copy of the court transcripts and determines whether the criminal conviction should be overturned (i.e., reversed), whether a new trial should be ordered (i.e., remanded), or whether the case's outcome should remain (i.e., affirmed).

TWO-TIERED VIOLENCE RISK ESTIMATES (TTV)

The TTV is a measure designed to assess the likelihood of future violence in offenders. It falls under the integrated-actuarial method of risk assessment, whereby an actuarial estimate is used as an anchor for the risk prediction, and dynamic risk factors are used for risk management purposes. Unlike other measures of an actuarial nature, the TTV was developed by evaluating common risk factors contained in existing risk measures, such as the Statistical Information on Recidivism Scale, as well as risk factors with a strong relation to violence in the literature. The scale was developed using a sample of 247 male offenders. Approximately half of the development sample reoffended in general, while around one third of the sample violently reoffended.

The TTV contains two subscales. The first subscale, the Actuarial Risk Estimate (ARE), consists of 10 historical items relating to an offenders' social and criminal history. Items relating to criminal history include age of first adult conviction, number of prior incarcerations, number of prior assault convictions, community supervision failure, and criminal associations. Items relating to social history include childhood antisocial behavior, adolescent antisocial behavior, history of alcohol abuse, failure to complete high school, and interpersonal difficulties. The majority of items are dichotomously scored as present or not present, with the exception of the age at first adult conviction, number of prior incarcerations, and number of prior assault conviction items.

Total scores on the ARE range from 0 to 13. The development sample obtained a mean ARE score of 8.3 (standard deviation = 3.3) with a standard error or measurement of 1.04. These total scores are associated with probabilities of recidivism at 6 months, 1 year, 2 years, and

3 years. For example, a total score of 13 is associated with a likelihood of violent recidivism of 37% after 1 year and 55% at 3 years postrelease. Confidence intervals are calculated for the total score for the ARE by adding and subtracting one point (the standard error or measurement for the measure) from the total score. The 95% confidence intervals provide the range of recidivism probabilities for the offender based on the offender's total score. For example, if an offender scores 6 on the ARE, the offender would then have a range of probable scores from 5 to 7. A score of 5 is associated with a probability of recidivism of 3.5% at 6 months postrelease, while a score of 7 would be associated with a probability of reoffending of 5.5% at the same time period. Therefore, it can be said that the probability of violent recidivism for this individual offender is between 3.5% and 5.5% within the first 6 months after release.

The second subscale, the Risk Management Indicators (RMI), consists of 13 items that have the potential to be dynamic in nature. The RMI items include aspects of the Central Eight risk factors, such as employment, substance abuse, family instability, associates, attitudes, and leisure, as well as other important dynamic risk factors, including financial, mental health, resistance to intervention, mood, social support, environment, and stressors. RMI items are scored as not present, present and requiring monitoring, or present and requiring intervention. The RMI can be periodically rescored in order to reflect changes in these dynamic factors due to treatment and interventions.

The ARE of the TTV correlates strongly with similar actuarial measures, such as the Statistical Information on Recidivism and the Violence Risk Appraisal Guide, obtaining correlation coefficients of over .60. The RMI has been shown to correlate strongly with similar dynamic measures, including the Risk Management scale of the Historical-Clinical-Risk Management-20, with correlation coefficients of over .60.

Validation research on the TTV has shown that it has moderate to high levels of predictive accuracy in predicting both general and violent recidivism in offenders. The common metric for evaluating predictive validity is with area under the curve values. This number gives the

likelihood that a randomly selected reoffender will have a higher score than a randomly selected non-reoffender. The ARE has obtained area under the curve values between .63 and .80 for violent recidivism and between .62 and .73 for general recidivism. The RMI has shown similar results in validation studies, obtaining area under the curve values between .58 and .80 for violent recidivism and between .62 and .75 for general recidivism. The interrater reliability of the TTV is high, with an intraclass correlation coefficient over .90 for both the ARE and the RMI. The TTV has yet to be validated in more diverse populations, for example, Aboriginal or female offenders.

U.S. DEPARTMENT OF HOMELAND SECURITY

Following the terrorist attacks of September 11, 2001, the U.S. Department of Homeland Security (DHS) was established as an Executive Department having a primary mission of preventing terrorist attacks within the United States. The Homeland Security Act of 2002 integrated all or part of 22 different federal departments and agencies into a single DHS. This entry focuses on the establishment and core missions of the DHS. In addition, it describes the partnerships that enable DHS to carry out its vision.

History

The establishment of a homeland security agency was contemplated prior to the terrorist attacks of September 11, 2001; however, legislation was not enacted until after that time. No federal agency had, as its primary mission, security of the homeland—the United States. Rather, responsibilities were dispersed among more than 100 governmental entities. On February 15, 2001, the U.S. Commission on National Security/21st Century (Hart-Rudman Commission) recommended significant actions necessary to meet national security challenges. In its Phase III Report, *Roadmap for National Security: Imperative for Change*, the commission identified the nation's vulnerability to terrorist attack and recommended the creation of a homeland security agency:

The combination of unconventional weapons proliferation with the persistence of international terrorism will end the relative invulnerability of the U.S. homeland to catastrophic attack. A direct attack against American citizens *on American soil* is likely over the next quarter century. . . . In the face of this threat, our nation has no coherent or integrated governmental structures. We therefore recommend the creation of an independent National Homeland Security Agency (NHSA) with responsibility for planning, coordinating and integrating various U.S. government activities involved in homeland security. (2001, p. viii, italics in original)

Consistent with its recommendations, on March 21, 2001, the National Homeland Security Agency Act was introduced in the House to establish the National Homeland Security Agency. Joint hearings were held on April 24, 2001; however, it was not until after the terrorist attacks of September 11, 2001, that legislation to create DHS was enacted.

Following the attacks, on October 8, 2001, President George W. Bush issued Executive Order 13228: Establishing the Office of Homeland Security and the Homeland Security Council. This order established an Office of Homeland Security within the Office of the President. The mission included developing and coordinating the implementation of a comprehensive national strategy to secure the United States from terrorist attack. It also included coordinating the Executive Branch's efforts to detect, prevent, and respond to terrorist

attacks within the United States. Executive action to further the administration's homeland security agenda was subsequently taken. Key actions included Homeland Security President Directive 1: Organization and Operation of Homeland Security Council (October 29, 2001), Executive Order 13260: Establishing the President's Homeland Security Advisory Council and Senior Advisory Committee for Homeland Security (March 21, 2002), and Executive Order 13267: Establishing a Transition Planning Office for the DHS within the Office of Management and Budget (June 20, 2002), in preparation for establishment of the proposed DHS.

Several bills were offered during the 107th Congress for purposes of establishing a national homeland security agency and combatting terrorism. On June 18, 2002, President Bush transmitted a legislative proposal to create the new cabinet-level department. Representative Richard K. Arney introduced the proposal, co-sponsored by 118 members of Congress, on June 24, 2002. The proposed legislation, with amendments, passed the House on July 26, 2002, and the Senate on November 19, 2002. On November 22, 2002, the House concurred with Senate amendments and the bill was forwarded to the president for action. The Homeland Security Act of 2002 was signed into law on November 25, 2002, establishing the U.S. DHS.

Homeland Security Act of 2002

The Homeland Security Act of 2002 established the DHS as an Executive Department of the United States. The primary mission of the DHS was to prevent terrorist attacks within the United States, reduce vulnerability to terrorism, and minimize damage and ensure recovery from attacks that occur within the United States. Terrorism is defined broadly as

any activity that (A) involves an act that (i) is dangerous to human life or potentially destructive of critical infrastructure or key resources and (ii) is a violation of the criminal laws of the United States or of any State or other subdivision of the United States and (B) appears to be intended (i) to intimidate or coerce a civilian population, (ii) to influence the policy of a

government by intimidation or coercion, or (iii) to affect the conduct of a government by mass destruction, assassination, or kidnapping.

The DHS's mission further included monitoring connections between illegal drug trafficking and terrorism as well as contributing to efforts to interdict illegal drug trafficking. In 2004, the act was amended to include a provision in the mission that the Department "ensure that the civil rights and civil liberties of persons are not diminished by efforts, activities, and programs aimed at securing the homeland."

Multiple agencies or components from the Departments of Justice, Treasury, Energy, Agriculture and Defense were transferred to the newly created department. The act provided that existing functions of those agencies transferred to the DHS were not to be diminished absent Congressional action. The responsibility for investigating and prosecuting acts of terrorism remained with the federal, state, and local law enforcement agencies having jurisdiction over the acts in question.

The act not only established DHS as a cabinet-level department but also sets in motion a massive governmental reorganization of agencies and functions, the significance of which had not occurred since the establishment of the Department of Defense following World War II. The legislation provided for numerous actions including establishing the structure of DHS with multiple directorates. It addressed the areas of information analysis and security, science and technology, emergency preparedness and response, and appropriate training. It also addressed the strengthening of air transportation and security, the coordination of communication between nonfederal entities, and the inclusion of the Secretary of DHS, subject to presidential direction, at meetings of the National Security Council.

Briefly, as of 2016, the following agencies carry out the day-to-day operations of DHS:

- *U.S. Customs and Border Protection* is the nation's largest law enforcement organization and is responsible for executing the front-line mission at and between international ports of entry.
- *Homeland Security Investigations/U.S. Immigration and Customs Enforcement (HSI/*

ICE) is responsible for criminal and civil investigation and enforcement of federal laws impacting homeland security including customs, trade, immigration, drug trafficking, terrorist financing, and more. HSI/ICE is further responsible for the detention and removal of illegal aliens.

- *U.S. Citizenship and Immigration Services* is responsible for immigrant and citizenship adjudications and benefits programs.
- *U.S. Coast Guard* is one of the five armed forces of the United States and the only military organization within the DHS.
- *U.S. Secret Service* is responsible for safeguarding the nation's financial infrastructure, protecting national leaders, and visiting heads of state, designated sites, and national special security events.
- *Transportation Security Administration* protects the nation's transportation systems to ensure the safety and freedom of movement for people and commerce.
- *Federal Emergency Management Agency* supports citizens and first responders in preparing for, responding to, and recovering from emergencies and disaster.
- *Federal Law Enforcement Training Centers* is the training arm of DHS. It provides law enforcement training to over 90 federal and state agencies, including all components of DHS.

The department further has multiple support components including the Management Directorate, the National Protection and Programs Directorate, the Office of Policy, the Science and Technology Directorate, the Domestic Nuclear Detection Office, the Office of Intelligence and Analysis, the Office of Health Affairs, and the Office of Operations Coordination. The Office of Operations Coordination is responsible for monitoring the security of the United States on a daily basis and coordinating activities within the DHS and with governors, Homeland Security Advisors, law enforcement partners, and critical infrastructure operators in all 50 states and more than 50 major urban areas nationwide. In addition, in 2015, DHS created the Office for Community Partnerships, focusing on countering violent extremism.

Core Missions

In the First Quadrennial Homeland Security Review Report in 2010, DHS recognized that while preventing a terrorist attack was the cornerstone of homeland security, the emphasis on terrorism did not capture the full range of threats and challenges—and that homeland security must take account of the need to engage the world through trade, travel, and other exchanges. In its report, DHS laid out three key concepts that formed the foundation for a comprehensive approach to homeland security: security, resilience, and customs and exchange. It further sets forth five core missions: The 2014 Quadrennial Homeland Security Review Report and 2014–2018 Strategic Plan continued to adhere to the five-mission structure of DHS, noting the need to continue to refine the missions to reflect the evolving landscape. The five core missions of the DHS are briefly summarized in the following subsections.

Preventing Terrorism and Enhancing Security

This core mission focuses on preventing attacks within the borders; preventing the unauthorized acquisition of chemical, biological, radiological, and nuclear materials within the United States; and reducing the vulnerability of critical infrastructure. DHS has identified 16 critical infrastructure sectors considered so vital that their incapacitation would have a debilitating effect on the United States. These sectors include energy and power sources, chemical, nuclear reactor, water, food and agriculture, communications, information technology, health care, transportation, financial services, among others. Because the private sector owns and operates the vast majority of the nation's critical infrastructure, DHS has established partnerships with the private sector to share critical information, resources, and mitigate risk.

Securing and Managing the Nation's Air, Land, and Sea Borders—While Facilitating Lawful Trade and Travel

A few examples of DHS' Fiscal Year 2015 enforcement efforts on this front include Customs and Border Protection's processing of 382 million

international travelers. Intelligence efforts prevented the boarding of over 11,000 high-risk travelers seeking to board flights destined to the United States. Domestically, the Transportation Security Administration screened more than 695 million passengers (approximately 1.9 million per day) and seized 2,500 firearms from carry-on luggage, 84% of which were loaded. The U.S. Coast Guard saved over 3,500 lives in search and rescue operations and seized cocaine and marijuana having a wholesale value of US\$4.3 billion in the maritime environment. HSI/ICE made 33,000 criminal arrests, including several thousand members of transnational gangs.

Enforcing and Administering the Immigration Laws

DHS's enforcement of immigration law is complex; Customs and Border Protection, HSI/ICE, and Citizenship and Immigration Services each maintains responsibility in this area. The enforcement of immigration laws may range from preventing the admission of an alien illegal attempting to enter the United States to the removal of a long-term resident alien convicted of serious crimes. DHS's priority for removal is focused on those considered border security or public safety threats.

Safeguarding and Securing Cyberspace

This mission includes assessing vulnerability to cyberattacks such as corporate security breaches, infrastructure, and other breaches impacting individual security and identity. DHS components including the U.S. Secret Service and HSI/ICE have specialized divisions dedicated to identifying international cyber criminals and combating cybercrime. Notably, HSI/ICE's Cyber Crimes Center further investigates individuals and organizations engaged in child pornography and child sex tourism. In 2015, HSI/ICE arrested approximately 2,400 alleged child predators.

Strengthening National Preparedness and Resilience

In the event of a terrorist attack, natural disaster, or other large-scale emergency, DHS provides a comprehensive federal response and works with

federal, state, local, and private sector partners to ensure an effective recovery effort. In 2015, the Federal Emergency Management Agency provided over US\$6 billion in federal assistance to aid communities recovering from natural disasters.

The Homeland Security Enterprise

The operations and functions of the DHS are carried out by more than 240,000 departmental and component agency employees as well as through partnerships with other federal agencies; state, local, tribal, and territorial governments; the private sector; and other nongovernmental organizations. These partners include those having responsibility for public safety and emergency response, owning and operating critical infrastructure and providing essential services, performing research, developing technology, and more. Public awareness and involvement is also important. DHS continues to encourage the public to be vigilant through the "If You See Something, Say Something" campaign and has established partnerships with organizations including, for example, the National Football League, Major League Baseball, and NASCAR, in an effort to raise public awareness at events and forums. Protecting the homeland is the primary responsibility of the DHS; it is accomplished not only through the effort of its employees but also through relationships and partnerships with other law enforcement, the private sector, and communities.

U.S. DEPARTMENT OF JUSTICE

Created in 1870, the U.S. Department of Justice (DOJ) is a federal executive department charged with enforcing the law and defending the interests of the United States in accordance with the law. The department's mission includes the following: ensure public safety against both domestic and foreign threats, prevent and control crime through federal leadership, seek punishment for those guilty of violating the law, and ensure the impartial and unbiased application of the law.

The DOJ is headed by the U.S. Attorney General who functions as the chief U.S. law officer. Other leadership positions within the DOJ include the Office of the Associate Attorney General, Office of the Deputy Attorney General, and Office of the Solicitor General. This entry describes each of these leadership positions; it then discusses the DOJ's strategic plan and organization.

U.S. Attorney General

The Office of the Attorney General was established by the Judiciary Act of 1789. This position of U.S. Attorney General was created as a one person part-time position. The Attorney General was charged with prosecuting and conducting all lawsuits on behalf of the United States in the Supreme Court. In addition, the Attorney General was tasked with providing legal advice and opinions about matters pertaining to the law to the U.S. President or upon request by the heads of other departments. Eventually, the workload became too much for one person, and as a result, several assistants for the Attorney General were hired.

As the nation grew, so too did the need to retain additional attorneys to serve the United States on legal matters, so private attorneys were retained to work on cases involving U.S. legal interests. After the end of the Civil War, the volume of litigation involving the United States increased, which resulted in the retention of an increased number of attorneys. To address concerns regarding the financial cost associated with retaining numerous attorneys and to add a permanent position, Congress passed the Act to Establish the DOJ in 1870.

With the establishment of the DOJ, all criminal and civil cases in which the United States was a party would be handled by the Office of the Attorney General. What was once a part-time appointment has now grown to become one of the largest law offices in the world. The duties of Office of the Attorney General include but are not limited to the following: act as representative of the United States in all legal matters; supervise and direct the divisions, boards, offices, and bureaus that make up the DOJ; provide both formal and informal advice and opinions on all legal matters to the President, the Cabinet, and heads of all executive departments and government agencies; provide recommendations to the President regarding federal judicial positions as well as positions within the department (these positions include U.S. Attorneys and U.S. Marshals); supervise or represent the United States in all legal matters both domestic and foreign; and perform duties as required by statute or Executive Order. The mission of the Attorney General is to supervise and head the operation of the DOJ including all of the

departments and divisions within the DOJ. As of August 2018, 84 Americans have held the office of Attorney General.

Office of the Deputy Attorney General

In 1950, the Office of the Deputy Attorney General was created by Attorney General James Howard McGrath. The Deputy Attorney General is the second highest ranking official in the DOJ. The Deputy General functions as the Chief Operating Officer for the department. U.S. Attorneys report directly to the Deputy General. The Deputy Attorney General is tasked with deciding on policy, legal, and operational issues. The mission of the Deputy Attorney is to assist and advise the Attorney General in creating and implementing department policies and programs as well as to supervise and direct the organizational components of the department.

In addition, the Deputy Attorney represents the DOJ at White House meetings with the National Security Council and Homeland Security Council to keep staff up-to-date. The Deputy Attorney also acts on behalf of the Attorney General to authorize searches and electronic surveillance as granted under the Foreign Intelligence Surveillance Act and Executive Order 12333 on Intelligence.

Furthermore, the Deputy Attorney General assesses and recommends whether to seek the death penalty on certain cases, acts as the initial contact with the White House on criminal matters, and recommends whether the President should grant petitions for pardon or commutation of sentence after consulting with the Office of the Pardon Attorney. Other duties include being responsible for all DOJ attorney personnel issues, coordinating the department's reaction to civil and terrorism-related conflicts, overseeing budgetary matters, and communicating those to Congress. In addition, the Deputy Attorney General sets enforcement priorities in consultation with the Attorney General, manages offices that reside within the department, shares oversight responsibility for the Office of Tribal Justice with the Attorney General, and performs other duties as assigned by the Attorney General.

Office of the Associate Attorney General

The Associate Attorney General is the third highest ranking official in the DOJ. The Office of the

Associate Attorney General was created in 1977 by Attorney General Order No. 699-77. The Associate Attorney General acts as part of the Attorney General's senior management team. The major functions of the Associate Attorney General are to assist the Attorney General and Deputy Attorney General with creating and overseeing DOJ policies.

The Associate Attorney General is charged with supervising the work of the following agencies and divisions: Antitrust Division, Civil Division, Civil Rights Division, Tax Division, and Environment and Natural Resources Division. The Associate Attorney General also oversees the Access to Justice Initiative, the Community Relations Service, the Executive Office for U.S. Trustees, the Office of Community Oriented Policing Services, Office of Justice Programs, the Office of Dispute Resolution, the Office of Information Policy, the Office on Violence Against Women, and the Foreign Claims Settlement Commission. Finally, both the Associate Attorney General and the Deputy Attorney General oversee the Office of Tribal Justice.

The Office of the Solicitor General

The Office of the Solicitor General was created in 1870 by the Statutory Authorization Act. The act states that the Solicitor General is to assist the Office of the Attorney General in the performance of its duties. The mission of the Solicitor General is to oversee appellate and other litigation matters on behalf of the United States in lower federal and state courts as well as represent the United States before the Supreme Court. The major functions of the Solicitor General include but are not limited to the following: supervise Supreme Court cases including appeals, petitions, briefs, and arguments; decide whether the government will file appeals; and determine when the United States should intercede to defend the constitutionality of an act of Congress. The Office of Solicitor General is also to assist the Attorney General, the Deputy Attorney General, and the Associate Attorney General on matters related to policy and programs per their request.

Specialized Divisions

In addition to the aforementioned leadership positions, the DOJ encompasses several specialized divisions, bureaus, and offices. These include the

following: Antitrust Division; Bureau of Alcohol, Tobacco, Firearms and Explosives; Civil Division; Civil Rights Division; Community Relations Service; Criminal Division; Drug Enforcement Administration; Environment and Natural Resources Division; Executive Office for Immigration Review; Executive Office for Organized Crime Drug Enforcement Task Forces; Executive Office for U.S. Attorneys; Executive Office for U.S. Trustees; Federal Bureau of Investigation; Federal Bureau of Prisons; Foreign Claims Settlement Commission; INTERPOL Washington—U.S. National Central Bureau; Justice Management Division; National Security Division; Office for Access to Justice; Office of Community Oriented Policing Services; Office of Information Policy; Office of Justice Programs; Office of Legal Counsel; Office of Legal Policy; Office of Legislative Affairs; Office of Professional Responsibility; Office of Public Affairs; Office of Tribal Justice; Office of the Inspector General; Office of the Pardon Attorney; Office on Violence Against Women; Professional Responsibility Advisory Office; Tax Division; U.S. Marshals Service; and U.S. Parole Commission.

Strategic Plan

The focus and strategic plan of the DOJ is guided by the current legal concerns and threats to the United States. As the number of federal offenses and civil lawsuits increased, so too did the scope of the DOJ. Congress expanded the duties of the department to meet the needs of the government.

Around the beginning of the 1900s, the government became increasingly involved in matters of social justice. As a response to the widespread belief that the government should intervene to create a sense of justice, Attorney General Charles Bonaparte created a group comprising former Secret Service agents and DOJ investigators, led by Stanley W. Finch, which would be named the Bureau of Investigation. This office is now known as the *Federal Bureau of Investigation*. In 1909, the DOJ established a criminal division that was charged with enforcing and overseeing the application of federal criminal laws.

The development of public lands influenced the creation of the Lands Division in 1910. Furthermore, antitrust laws created a necessity for specialized divisions. In 1933, the DOJ underwent a major reorganization, resulting in the expansion

of several divisions including the Tax Division and the Antitrust Division. The department continued to expand, and in 1940, the Immigration and Naturalization Service office was moved from the Department of Labor to the DOJ. In 1957, during the civil rights movement, the department created a Civil Rights Division in order to enforce federal laws that prohibit discrimination.

During the 1960s, the drug trade began to emerge as national concern. In 1972, President Richard Nixon created the Office of National Narcotics Intelligence and the Office for Drug Abuse Law enforcement to address issues of drug trafficking. However, the following year, Nixon combined five federal drug enforcement agencies to form what is now known as the *Drug Enforcement Administration*, which is housed under the DOJ. Shortly after the terrorist attacks on September 11, 2001, the DOJ focused its attention on combatting terrorism. The department has grown and continues to grow to accommodate emerging legal issues, domestic and foreign national threats.

U.S. SECRET SERVICE

On July 5, 1865, the U.S. Secret Service (USSS) was created to prevent and investigate counterfeiting. This entry discusses the history of, careers within, and training for the USSS.

Initially, the USSS was a division in the Department of Treasury (Secret Service Division). At the time of its creation, it was only one of four federal law enforcement agencies, along with the U.S. Post Office Department's Office of Instructions and Mail Depredations (now the U.S. Postal Service Inspection Service), U.S. Park Police, and the U.S. Marshals Service. Because the U.S. Marshals Service was small in number, the USSS was often tasked to assist them in investigating other types of criminal activity, including murder, bank robbery, gambling, and other felonies. In 1867, the USSS was charged with helping detect frauds against the government. Investigations were conducted against moonshiners, smugglers, the Ku Klux Klan, individuals committing mail robbery and land fraud, among others. In 1877, Congress made it illegal to counterfeit coins, gold bars, and silver bars and gave the USSS responsibility for investigating those crimes. After President William McKinley was assassinated in 1901, Congress requested the USSS to begin presidential protection duties, a task formally started in 1902. In 1906, the USSS was given the task of investigating western land fraud, a tremendous problem in the recently settled west. These investigations resulted in thousands of acres being rightfully returned to the United States. Prior to the creation of the Federal Bureau of Investigation in 1908, the USSS also conducted intelligence and counterintelligence operations.

In 1922, the White House Police were created, which today is the Uniformed Division of the USSS (per Public Law 71-221 of 1930). In 1970, it was renamed the Executive Protective Service and given the duties of protecting diplomatic missions in Washington, DC. In 1934, the Treasury Guard Force (today the Treasury Police Force) was created and added to the USSS. The ultimate value and worth of the USSS came to the fore in 1950, when two Puerto Rican nationalists tried to assassinate President Harry Truman at Blair House in Washington, DC. Truman was living in Blair House, while the White House was undergoing a major renovation. On November 1, Oscar Collazo and Griselio Torresola approached the house from different directions and engaged in a gun battle with White House Police and USSS agents. During the gun battle, Police Private Leslie Coffelt was killed, and Officers Donald Birdzell and Joseph

Downs were wounded. Coffelt killed Torresola. Collazo was arrested and sentenced to death (later commuted to life by Truman and then commuted by President Jimmy Carter; he died in Puerto Rico in 1994). As a result of this attack, Congress authorized the USSS to protect the president, president's immediate family, vice president, and president- and vice president-elect.

On November 22, 1963, the American public became acutely aware of the work of the USSS, when Lee Harvey Oswald shot and killed President John F. Kennedy. Kennedy was in Dallas, TX, traveling in an open convertible with his wife, Texas Governor John Connally, and Connally's wife, when Oswald opened fire. Agent William Greer was driving the limousine, with Agent Roy Kellerman in the front seat. At the sound of the first shot, Agent Clint Hill, riding on the car behind, ran and jumped over the trunk of the limousine and placed his body over that of the first lady and president, shielding them with his body all the way to Parkland Hospital. The video and still images revealed to the American public (and the world) the bravery and courage of Secret Service agents, the extent to which agents would go in the discharge of their duties, and their heroism in fulfilling their sworn duties.

The training, professionalism, and heroism of the Secret Service were again revealed on March 20, 1981, when John Hinckley Jr. attempted to assassinate President Ronald Reagan. Reagan had given a speech at the Washington Hilton Hotel and was being escorted about 30 ft to his car when Hinckley jumped out of the crowd and, in approximately 2–3 s, fired six shots from a .22 caliber pistol. Press Secretary James Brady was shot in the head, Washington DC Police Officer Thomas Delahanty was shot in the neck, and Reagan had a bullet enter his chest below the left arm (after ricocheting off the limousine). Virtually instantaneously, Special Agent Tim McCarthy spread himself over Reagan and was shot in the abdomen. In those same couple of seconds, Special Agent Jerry Parr pushed Reagan into the limousine and lay spread-eagle over him. Initially, the president thought he had broken a rib when the agent shoved him in the car, but he then started coughing up blood. He was rushed to George Washington Hospital where he ultimately recovered. In the mere blink of an eye, two special

agents did what years of training had taught them, with no thought of their own life or safety.

On September 11, 2001, the United States experienced the greatest domestic terrorist attack in its history. The New York Field Office was housed in Building 7 of the World Trade Center and was destroyed along with the Twin Towers, killing one USSS employee. Shortly after, President George W. Bush signed into law the U.S. PATRIOT Act. As part of the law's mandate, the USSS designated eight major metropolitan areas as part of an Electronic Crimes Task Force across the United States. In 2002, the U.S. Department of Homeland Security was established, and on March 1, 2003, in one of the most significant shifts in the history of the USSS, the Secret Service was transferred from the Department of the Treasury to the Department of Homeland Security. As part of that shift, the Secret Service was given a major role to play in protecting the United States from terrorism, terrorist activity, and cyberterrorism. This was in addition to their ongoing duties in executive protection and investigations. From cyber investigations to financial crimes to counterfeiting to intelligence gathering and analysis, the Secret Service was placed on the front line of homeland security.

Today, the Secret Service has approximately 3,200 special agents throughout the world, 1,300 Uniformed Division officers, and 2,000 other employees. They are spread throughout 150 offices in the United States and abroad. Their executive protection division is charged with protecting the president, vice president, and their immediate families; former presidents, their spouses, and minor children under 16 years; foreign heads of state and spouses when visiting; major presidential and vice presidential candidates and spouses; and personnel taking part in National Special Security Events as designated by the U.S. secretary of homeland security.

In their storied history, 36 agents have made the ultimate sacrifice for their country. Some were killed in accidents, but the majority were murdered. The first agent to die in the line of duty was Operative William Craig on September 3, 1902, in an accident between the president's carriage and a street car. The first female agent to be killed in the line of duty was Special Agent Julie Cross, who was killed by two assailants on June 4, 1980, in Los Angeles, CA. Six personnel were killed on April 19,

1985, in the bombing of the Alfred P. Murrah Federal Building in Oklahoma City, OK. One employee, Master Special Officer Craig Miller, died at the World Trade Center on September 11, 2001.

Careers With the Secret Service

The USSS has four job classifications:

- Special Agent
- Uniformed Division Officer
- Special Officer
- Administrative/Professional and Technical personnel

The most sought after and demanding is the special agent role. These individuals serve in investigations and executive protection. Special agents conduct investigations, including counterfeiting, other financial crimes, computer crimes, cyberattacks on U.S. financial institutions and telecommunications, intelligence gathering and analysis, and identifying other threats to national security and U.S. leaders. The Secret Service National Threat Assessment Center is responsible for conducting threat assessments, targeting violence assessments, standardizing threat assessment across law enforcement agencies, facilitating information sharing between agencies, and training law enforcement at all levels of government. As part of those responsibilities, they publish an open-source summary of attacks on government facilities and officials that offer information that can be shared among law enforcement to mitigate threats. Information in the summaries includes identification of perpetrator behaviors and appropriate preventive interventions, finding links between actor mental health and motives and behavior, identifying actor stressors and stress management techniques that can be used by law enforcement, suggestions on security plans (especially useful for schools), and techniques of intelligence analysis as a preventive tool.

The selection criteria for special agents is some of the most stringent in federal service. Some of the requirements include

- being a U.S. citizen between 21 and 37 years of age;
- having vision no worse than 20/60 binocular, correctable to 20/20;

- passing a stringent written examination;
- passing a rigorous Applicant Physical Abilities Test;
- having excellent health;
- being able to qualify for a Top Secret clearance;
- passing a comprehensive background investigation that includes in-depth interviews, drug screen, medical exam, and polygraph; and
- having no visible body markings, such as tattoos, body art, or branding.

The Uniform Division protects facilities and venues for protectees, the White House complex, the Naval Observatory (vice president's residence), Treasury Department building, and foreign diplomatic missions in Washington, DC. In addition to their regular law enforcement duties, officers can be assigned to K-9, Emergency Response Team, Countersniper Team, Motorcade Support Unit, Crime Scene Search Unit, and Special Operations Section. To be considered for a position as an officer, applicants must

- be a U.S. citizen;
- be 21–37 years old;
- have correctable vision to 20/20;
- be in excellent health;
- complete the Applicant Physical Abilities Test;
- complete a comprehensive written exam;
- pass various interviews;
- qualify for a Top Secret clearance;
- pass a background investigation; and
- have no visible body markings.

Special Officers staff security posts, inspect and maintain USSS vehicles, drive protective and following vehicles, control movement of persons at Secret Service facilities and areas, and monitor communications and X-ray equipment. Special Officers are commissioned law enforcement personnel and have full arrest powers. Selection requirements are similar to those of Uniformed Division officers.

Administrative/Professional and Technical personnel are civilians within the USSS and perform a myriad of functions in support of the USSS mission. They may be accountants, chemists, criminal research specialists, investigative analysts, attorneys, photographers, information technology specialists, engineers, fingerprint

specialists, document analysts, or security specialists, among many other jobs.

Training

Secret Service agents are some of the most highly trained personnel in law enforcement. Agents begin their training at the Federal Law Enforcement Training Center in Glynco, GA, then go to the James J. Rowley Training Center near Washington, DC, for 18 more weeks of training. At Federal Law Enforcement Training Center, agents are trained in a variety of law enforcement areas, including firearms, psychology, criminal law, arrest/search/seizure, self-defense, international treaties, diplomatic immunity, and other law enforcement areas. At the training facility in DC, agents are given advanced training in investigative procedures, counterfeiting techniques, access device fraud, financial criminal activity, protective intelligence investigations, physical protection techniques, protective advances, and emergency medicine. After their initial training is complete, agents receive continuous training throughout their career. Not only do agents receive refresher training in courses already completed, they also receive advanced instruction in a variety of topic areas related to terrorism, financial and money crimes, cybercrime and security, and protection.

Throughout its storied and illustrious history, the USSS has been at the forefront of protecting presidents and other critical personnel from harm, often placing their own lives in jeopardy to do so. They have had a major impact in reducing counterfeiting and financial crimes, keeping the country financially stable, and protecting U.S. financial interests. They have served a critical role in cybersecurity and cybercrime, preventing terrorists, organized criminal enterprises, foreign governments, and other individuals from attacking the country's computer infrastructure. There is no doubt that they will continue to do so in the coming years.

UNDERCOVER POLICING

Undercover policing is the process by which an officer removes the trappings of his or her office, such as one's badge, uniform, and presence, in order to engage in sanctioned actions of a quasi-legal or illegal nature to collect evidence on crimes, which may otherwise go undetected by traditional police methods. An undercover officer may be present before or during the commission of a crime and purposefully not intercede. Undercover work typically focuses on consensual crimes (e.g., a drug purchase, prostitution), crimes where the criminal is difficult to locate (e.g., pick pockets, purse grabbers), or complex crimes that are difficult to detect (e.g., well-organized criminal groups, political corruption). The officer engages the targeted criminal, often with the help of informants or information collected through traditional police methods. Using the undercover team, subtlety, guile, and misrepresentation of the self, the undercover officer observes that the individual commits crimes or records admission to crimes. Engaging of a target can vary, from the simple attempt to purchase a controlled substance from a dealer to the complex crafting of a false persona with the help of an informant to gain access to organized crime's inner circles. Traditional goals of an arrest may be bypassed for secondary benefits, such as intelligence gathering on logistics, finances, connections, and more. This entry focuses on the history of undercover policing, traditional undercover processes, and the risks of undercover work.

History

Modern undercover tactics were created by Eugene Francois Vidocq in the early 19th century.

Historically, Western countries have resisted law enforcement's involvement with any criminal element to the point where even detectives interviewing criminals were viewed with suspicion. Vidocq employed former criminals and paid them to collect information from strategic places like prisons. The Pinkerton National Detective Agency, founded in Chicago, IL, in 1850, expanded on Vidocq's tactics, having undercover agents accompany the criminals into criminal situations to observe and later report. Currently, undercover work with police generally involves the criminal or confidential informants introducing the officer to the contact, gang, or the target of the operation, and then, the criminal or confidential informant is phased out of the operation.

The first federal police force in the United States to use undercover tactics was the Secret Service in 1865, which borrowed methods and hired personnel from private police like Pinkerton. The viewpoints on the government's approval and use of undercover operations have varied from *reprehensible* to *necessary evil*. In 1936, the Federal Bureau of Investigation announced that it would not enter into any illegal compacts or pursue illegal courses of action, no matter the outcome or ends served. By 1972, the Federal Bureau of Investigation had increased its use of undercover operations, as did the Internal Revenue Service in 1982; the Bureau of Alcohol, Tobacco, and Firearms in 1968; and other federal investigative departments soon after.

Historically, the courts have ruled that undercover tactics are constitutional within the United States. Undercover tactics emerged due to the limitations of traditional confession extraction, to create a fair playing field and to achieve an increase in discovery and conviction of white-collar crime and corruption. Furthermore, changes in criminal liability have emphasized the state of mind of the accused criminals, rather than actual product. This has allowed legal items, such as sugar or electronics, to be misrepresented as narcotics or stolen goods, and the individuals involved can be charged because they believed they were entering into an illegal arrangement.

Currently, undercover work has been estimated to occur more often on the federal level than the state, detective than patrol, and private police than public police. Undercover work appears

more likely to target consensual, recurring, and organized exchanges where a victim or witness was lacking, unaware of the illegal nature of the situation, or unwilling to come forward.

Standard Procedures

Undercover operations follow a standard operational pattern: selection, training, planning, deployment, decompression, and reintegration. Functional undercover operations often require the relaxing of department rules, such as hourly check-ins and not drinking alcohol on the job, as well as customs and practices (e.g., dress codes). Department flexibility for the undercover officer is necessary for the officer to adapt to the criminal milieu.

Selection most often occurs among newer officers who have not developed traditional police habits which may give them away, although a strong understanding of the law is necessary to avoid issues like entrapment. Field operator selection is recommended to be volunteer only, from among the ranks of those officers who see value in the methods and who are not attempting to escape an unwanted situation, and to take place post training. Post-training selection research has found that extroverted and emotionally stable are the best fit for this type of work. Undercover work is comparable to other special units in that not everyone is fit for the job. Selection should utilize all available information, but the ultimate decision lies with the officers after they have received psychological and physical assessments and been provided a full disclosure of the costs and consequences of undercover work. Assessments should be no older than 6 months due to the changes that may occur in that time period.

Training of undercover officers simulates real-life situations as closely as possible, with a stepwise increase in process to allow officers to absorb fundamental lessons before moving onto more complex deceptions. Current and former undercover officers bring real-world scenarios and current intelligence into their training. Training can reflect the type of operation and includes intelligence, prevention, or facilitation. Intelligence focuses on the collection of information before or after a crime has occurred (e.g., who was involved in illegal activity). Prevention focuses on stopping

crime or harm from happening (e.g., replacing explosive substances with inert ones). Facilitation can be the encouragement of individuals to act or not preventing a crime from occurring but instead observing the actors involved (e.g., joining and encouraging a radicalized political group).

Planning and deployment are often cyclical, due to the need for operator adjustments and operational changes. Planning may involve the creation of a false persona and verifying documents, the use of criminal informants to help place the officer within an organization, or the fabrication of a criminal situation to see who walks into the trap. Psychological and physiological maintenance of the officer is paramount as the undercover process creates a relationship between the officer and the target, effectively humanizing the individual, while compounding stress. *Going native* (i.e., becoming a criminal) is a severe but infrequent occurrence due to the stress and the relationships of the undercover officer. Lesser effects, including expressing doubts about the operation, questioning the department, and experiencing psychological problems, are more common. Successful deployment will depend on many factors, particularly the definition of success as determined by the focus of the operation. Although many undercover operations do not end with arrests due to the purpose of the operation (e.g., intelligence gathering), opportunity and chance also play a large role in effective undercover work. Despite the best effort of the undercover officer, an arrest may not be possible.

Decompression and reintegration occurs after the operation is over, when the officer sheds his or her false persona, experiences a psychological and physiological rebound due to the strain of the operation, and returns to mainstream work. This process can be difficult and may take up to 2 years. There is a dramatic increase in officers leaving the force following undercover work. Discipline issues while undercover have been noted to increase the rate at which officers leave the force following their undercover work as well as increase the chance of being involved in criminal actions following their departure.

Financing for undercover programs often comes from the operations themselves. Seized goods and funds are one source, but the intent of the operation may result in additional funding. For

example, one Fish and Wildlife Department operation *sold* multiple rare birds, collected payment, and arrested the would-be buyers.

Risks

Risks come in the form of proximity, strains, and investigative practices, which may be harmful to the officer. Physical proximity with criminals creates increased risk due to officers being stripped of the trappings of their profession (i.e., badge, body armor, and weapon). In undercover work, most deadly encounters occur with officer and assailant fewer than 6 ft from each other. Since emotional proximity can occur when officers humanize criminals whom they have come to know and may care for, undercover officers are assigned supervisors who work closely with them to maintain emotional distance, as officers may begin to question the department, the operation, and themselves. This can progress to the point where an officer turns from the law and goes native. All officers must consider the consequences, both professionally and morally, of what would happen if they were to commit a crime while undercover.

Progressive undercover programs have been known to include family education during selection due to the impact undercover work has on families, with the risk carried by the relationships. Officers must often miss family events due to operational demands, and even when present, they may not be able to fully discard the undercover persona (e.g., a beard, tattoos). Officers may need to attend family functions or take photos bearing the trappings of the criminal life.

Investigative artifacts, where the act of investigating creates crime, is a serious concern. This concept is demonstrated by the question driving the investigation: Originally, it was “Is he or she corrupt?” Then it changed to “Is he or she corruptible?” For example, John DeLorean was persuaded by an informant that he could save his company from bankruptcy by bankrolling a cocaine shipment. Another example uses a double catch, where a public official is offered a bribe by an undercover officer. Taking the bribe is obviously illegal, but failing to report the attempted bribe can also be illegal. No undercover operation, no crime. Artifacts may also take the form of an individual who does not possess the means or

capabilities to commit a crime but who can when provided with inducement and equipment. For example, an individual noted for viewing extremist rhetoric was contacted by an extremist group to help plant a bomb. After meeting with local representatives and provided a device, the individual attempts to plant it and is promptly arrested, even though the extremist group representatives, bomb, and possible motivation for the act were all part of an undercover operation. Officers’ influence may affect not only an individual but also groups of people. In Germany, 15% of a radical political group’s leadership positions were occupied by police and intelligence departments, each undercover agent being unaware of the others. Due to possible influence by the agents on the actions of the group, the courts were unable to determine how the group may have acted without that influence.

Another risk of undercover work is the overzealous use or misuse of undercover tactics. Political examples range from the Watergate scandal to the spying on political groups in the United States in the 1960s. Misuse of tactics may lead to entrapment, where the officer proposes illegal actions or provokes a crime, and the criminal is provided protection by the courts due to misuse of the tactics. Even if a tactic is properly used initially, an undercover officer may be frustrated or pressured to find crime or intelligence, leading to either overzealous use or misuse on the part of the officer.

Ethical Concerns

While many complex issues and risk are left unnoted, the last point of discussion will be ethical concerns of undercover work. Ethically, the primary focus is on whether it is acceptable for the government to employ deceptive tactics and who should be the target of such tactics. Should the government deceive people, even if for good reasons? Who should undercover tactics be used on, with possible targets including drug dealers, politicians, and police officers suspected of corruption?

VANDALISM

In many countries, vandalism is one of the most common forms of criminal transgression but also one of the most puzzling since the attack of property for no obvious material gain needs attention in explanatory terms. The notion of vandalism derives its meaning from an East German tribe known as the *Vandals*, who became infamous during the 4th and 5th century CE for their invasion and destruction of cities across Western Europe. The Vandals pillaged, looted, raped, and murdered on their path to colonial expansion. The Sack of Rome in 455 was the height of their notoriety and military success. By 534, the Vandal King Gelimer had been forced to surrender to the Romans, and this act effectively brought an end to the Vandal Empire. However, it was not until the 19th century that the term *vandalism* came to refer to property destruction rather than a tribe of people. This entry explores in further detail (a) vandalism in contemporary society, (b) a typology of vandalism for the 21st century, (c) international comparisons, (d) explanations for vandalism, (e) theories on how to prevent and reduce vandalism, (f) a challenge to conventional wisdom on vandalism, and (g) vandalism in the future.

Vandalism in Contemporary Society

The label of *vandalism* ordinarily refers to the intentional or reckless destruction or damage to property that does not belong to oneself. In

practice, police officers, as agents of law enforcement, have discretion to decide what actually constitutes *permanent* or *nonpermanent* damage.

One of the primary data sources most used in order to attempt to forge a comparative perspective is the International Crime Victimization Survey, which collates data from a diverse range of nations. This is not without problems, however, due to different definitions and data sets across countries.

Across Europe and the United States, it is generally recognized that some forms of criminal damage are significantly more serious than others; thus, vandalism encompasses a diverse range of acts. As well as destroying property, some acts of vandalism can endanger human life. In England, the Criminal Damage Act 1971 prescribes a maximum sentence of life imprisonment for the latter, including arson. The seriousness of vandalism is thus more often related to the cost of the damage rather than the motivations of the offender, which is a fundamental underpinning of English criminal law. Acts of vandalism are diverse, thus encouraging the formulation of a typology as developed by Matthew Long and Roger Hopkins Burke.

Long and Hopkins Burke's Typology of Vandalism for the 21st Century

Exploratory vandalism is typically committed by children under the age of criminal responsibility, which means they cannot be prosecuted because they are minors. Examples include children breaking things by throwing stones or with the use of

instruments (e.g., a catapult) to target objects for destruction. Ordinarily, those committing this form of vandalism are perceived to do so in a joyful and somewhat innocent spirit. There is a lack of full cognition about victims and consequences of actions and certainly no premeditated malice.

Drift vandalism tends to be committed in groups by youths in the phase of adolescence, which straddles the transition from childhood to full adult status. Damage committed by these so-called delinquent youths is often censured as being *random* and *mindless*. In reality, this type of property damage is invariably systematic and, more often than not, meaningful to the perpetrators. This kind of vandalism may typically be targeted against certain objects that have a symbolic status and value in our culture (e.g., automobiles). In certain social contexts, property damage is not only targeted, but it is almost expected to occur. One such example is teenage house parties where routine damage to household items, including furniture, is most certainly normalized if not actively encouraged.

Collateral vandalism, although deliberate, is almost incidental to the commission of a more serious crime. In previous decades, such acts have included the destruction of public telephone booths during a theft of cash contained within them and are driven by a motivation of acquisition. This motivation may be overtly materialistic (e.g., the theft of lead from the roof of a church) or acquisitive in the sense of obtaining a trophy (e.g., the student who steals a traffic cone to take it home to display).

Hate vandalism may be born out of spite or a desire for revenge such as ex-partners seeking to destroy each other's cars or homes. Yet such vandalism takes on more regressive, politically motivated connotations when its victims are members of culturally referenced groups related to race, religion, sexuality, disability, mental health, or indeed any area of diversity.

International Comparisons

As previously indicated, it is difficult to make international comparisons of exploratory and drift vandalism because of the variable age of criminal responsibility. There are great variations across Europe itself; for example, the age of

accountability is 13 in France and 18 in Belgium. In the United States, 13 states have set ages of criminal responsibility ranging between 6 and 12 years of age. Most states rely on common law, which holds that from ages 7–14 years, children cannot be presumed legally responsible but can be held accountable. Thus, there is wide variation in terms of whether children in some states are subject to the full force of the law, whereas in another state, they may avoid criminal sanction.

Across many Western cultures, the automobile appears to be a target of destruction. Take, for example, the craze of tipping cars into the canals of Amsterdam in the Netherlands. In terms of context, student-led vandalism is common across cultures. One example of student-led vandalism is the notorious Skulls and Bones Society at Yale University, which had a reputation for *crooking*, namely stealing items from campus buildings.

Japan has experienced a significant increase in metal thefts, including incense holders in graveyards and copper wiring in recent years. This increase has been attributed to the economic growth of China and associated demand for material that it is unable to produce. Although much of these thefts are driven by the profit motive, damage does occur. Such damage done is *collateral* in the sense that it is incidental to the initial act of acquisition.

Racially and religiously motivated vandalism has been common in Europe. In France, home to the largest Western European Jewish population, synagogues have been attacked, Swastikas daubed on property, and graves desecrated. In Palestine, hate vandalism is characterized by the stone throwing of children against military tanks or bulldozers in protest of the Israeli occupation of territories.

Political vandalism has been rife in the United States with groups such as the Animal Liberation Front periodically engaged in targeted property destruction since the 1980s. In Japan, traditionally characterized as a low-crime society, there was a spate of flower destruction in 2008, which was a political response to an oppressive social order.

Explaining Vandalism

The exploratory and drift vandalisms of the young can be explained by the conception of crime as a

function of opportunity. What *routine activities* theory fails to explain, however, is why some people transgress and others do not. This kind of vandalism ordinarily has a subcultural component, as first articulated by Albert Cohen in his seminal work on gangs, and is something in which David Matza observed that young people tend to grow out of as they get older and take on responsibilities such as work, marriage, and family.

It is precisely because of its acquisitive nature that collateral vandalism can be explained by recourse to *rational actor* model theories. There is thus an assumption that prospective offenders calculate whether there is more to be gained than lost when deciding whether to commit a particular offense. At the heart of these theories is a conviction that offenders use an economic cost-benefit style analysis. Furthermore, Robert Merton's classic work around the *strain* (i.e., what happens when some people do not feel they have the institutionalized means to achieve cultural goals) helps explain this materially motivated mode of vandalism.

It is important to look beyond conventional criminological explanations in order to understand hate vandalism because hate is born of deeper societal prejudice. Some Freudians argue that hate vandalism actually targets the *displaced* rather than the *real* targets of resentment, due to unresolved conflicts locked deep in the psyche. Social psychologists would nevertheless be cynical of attempts to reduce the roots of hate vandalism to that of individual pathology. More specifically, social identity theorists have pointed out that if hate is born of prejudice, then this often stems from competition between social groups for scarce resources.

Preventing and Reducing Vandalism

Crime prevention interest has centered on conventional drift vandalism typically committed by those in their teenage years. There is an implicit acceptance that the commission of vandalism and other relatively minor transgressions is a normal part of growing up. Rather than attempting to change the person, much attention has been directed to changing the environment to make it less likely that these kinds of offenses can occur. Situational crime prevention, which seeks to design out crime and target hardening measures,

has predominated since the 1980s, underpinned by rational choice and routine activities theories. In the context of car vandalism, for example, the creation of side mirrors that fold in was designed to make them less-visible targets of vandals.

Challenging Conventional Wisdom on Vandalism

Radical criminologists would argue that the acts of vandalism largely pale in significance when compared to the more harmful practices engaged in by the state and big business. The kind of collateral damage which is the outcome of warfare, for instance, may not only involve the immobilization of military bases but also devastatingly lead to the loss of tens or even hundreds of thousands of lives (e.g., Vietnam in the 1960s, Cambodia in the 1970s, and the Gulf conflicts beginning in the 1990s).

In being *Passionate about protecting the Earth*, Greenpeace has campaigned against environmental destruction, often gaining political enemies in the process. The 1985 sinking of its ship *Rainbow Warrior* in the South Pacific off the coast of New Zealand resulted in a fatality. Others have controversially argued that winning the right to host mega events such as FIFA World Cup or the Olympics Games has been the catalyst for large-scale developments that have been massively disruptive to respective local populations and have had an adverse impact on property destruction and reconstruction in certain areas of the cities concerned.

Those drawing on neo-Marxist perspectives propose that the law is created in order to serve the interests of the ruling elite in society. This means that state vandalism is underpinned by sectional political ideology (e.g., collateral damage in war may be justified by the interests of protecting national security). So from this perspective, those who may be censured by the state as vandals (e.g., environmental activists or anti-globalization protestors) are reconstituted as prosocial political actors, attempting to reconfigure a more equitable, sustainable, and just social order.

Vandalism in the Future

It is thought that by 2018, around half of the world's population will have Internet access. What

has become known as *cybercrime* manifests itself in many ways through the use of mediated technologies. One of the most common forms of cyber vandalism is hacking, which typically involves the shortcutting of a computer-generated system. This mode of vandalism has been facilitated through the fast-growing, mass availability of personal computers since the 1980s and is centered on crimes of acquisition (e.g., pirated commercial software). In the early part of the 21st century, online vandalism has affected personal, commercial, and governmental websites. Commonly, crimes have included the posting of graffiti on online images of buildings and monuments and attaching pornographic images to online architectural structures. Crimes of acquisition remain prevalent with *spyware* targeting business or personal data and *phishing* involving attempts to get victims to divulge sensitive financial or personal information. Hatred is often a motivation for *Crackers*, who use malicious software known as *malware*, which releases viruses and worms into individual operating systems in order to intentionally damage data and often hard drives. Many terrorist experts predict that the next major attack will involve cyberterrorism.

VETERANS COURTS

Veterans courts are a type of specialty criminal court for military veterans who have been arrested. They are closely modeled after drug treatment and mental health courts. The aim of the courts is to rehabilitate military veterans using treatment and services to improve mental health, reduce substance misuse, and reduce future criminal recidivism. This entry begins with a summary of justice involved military veterans and then provides a brief introduction to the veterans court model including key components, theoretical underpinnings, and a discussion of the impact of veterans courts on participants. The entry concludes with a short overview of the critiques of the veterans court model.

Military Veterans in the Criminal Justice System

Accurate estimates of the number of military veterans in the criminal justice system (i.e., arrested, on probation, and in jails or prisons) are difficult to obtain given inconsistent practices with regard to asking for veteran status within criminal justice settings and the varying approaches to data collection (e.g., self-reported veteran status vs. use of administrative records). Given the limitations, the best estimate available suggests that approximately 10% of people who are arrested and incarcerated in the United States are military veterans. Among veterans who have been arrested, many experience symptoms of post-traumatic stress disorder, have traumatic brain injury, struggle with substance use problems, or have co-occurring disorders. In fact, an estimated 70% of justice involved veterans have a substance use disorder. The vast majority of veterans will never be arrested or incarcerated. The veterans who do

have contact with the criminal justice system, however, face significant and disproportionate risk of suicide and exacerbation of psychiatric and physical health symptoms during incarceration. Due to the risks faced by justice involved veterans and the prevalence of veterans within the criminal justice system, stakeholders supported the development and implementation of veterans courts, first established in 2004 in Anchorage, AK. Shortly after, Judge Robert Russell created a veterans court in Buffalo, NY, which is the model for veterans courts across the United States.

Veterans Court Model

Veterans courts, like other specialty courts, are based on the foundation of therapeutic jurisprudence, which postulates that contact with the criminal justice system has the potential to harm or help a person's emotional, behavioral, and mental health. As a means to enhance the therapeutic impact of courts, specialty courts help participants by connecting them with treatment and services to improve mental health and/or substance misuse issues. In veterans court, participants live in the community and are required to take part in highly structured, intensive substance use and mental health treatment rather than serve time in prison. Participants are supervised by an interdisciplinary team of legal and mental health professionals including a judge, court administrators, lawyers, probation officers, community providers, and veteran justice outreach specialists. Veteran justice outreach specialists, employed through the U.S. Department of Veteran Affairs, are responsible for connecting veterans court participants to benefits, coordinating care, and providing case management services.

Participation in veterans court is voluntary. Potential participants can be referred by veteran justice outreach specialists, attorneys, judges, correctional staff, community providers, or self-referral. Eligibility varies from jurisdiction to jurisdiction with regard to charges, military discharge status (i.e., whether a veteran received an honorable discharge), and combat exposure that will qualify an offender to participate. For example, some veterans courts will accept only veterans who are eligible for benefits and services through

the Veterans Administration, while others restrict participation to veterans who experienced combat trauma. The veterans court team supervises court participants' compliance with court orders and adherence to treatment through regular court hearings before the judge, random drug testing, weekly meetings with probation officers, and staff meetings. Veterans court participants take part in numerous services including individual and group mental health and substance use treatment, psychotropic treatments, 12-step and peer-run groups, vocational training, compensated work therapy, Moral Reconnection Therapy, and housing programs. The duration of veterans court participation varies from court to court and participant success. Most programs are approximately 1–2 years in duration.

Although veterans courts are similar to drug treatment and mental health courts, there are three key differences. First, veterans courts intentionally promote and facilitate bonding and camaraderie between court participants by recognizing, referencing, and building on participants' shared histories of military experience and the military culture. Second, veterans courts include a mentoring component; each veterans court participant is paired with a veteran mentor. The mentor offers friendship, emotional support, and guidance throughout court participation. Finally, veterans courts work closely with the Veterans Administration. Thus, veterans courts' participants tend to have access to more resources than typical criminal defendants.

The Impact of Veterans Court

Research on the impact of participation in veterans courts on mental health, substance use, and criminal recidivism is limited. Like other research involving specialty courts, randomization to the court is often not possible. Therefore, discerning the impact of the specialty court and bias resulting from voluntary participation in court programming is challenging. Given this challenge, preliminary reports on veterans courts do show improvements in mental health including reductions in psychiatric symptoms and substance use during and following veterans court. It remains unclear if veterans court participation reduces future criminal offending among veterans.

A Critique of Veterans Court

Critics charge that veterans courts, like other specialized courts, give rise to due process concerns, as many jurisdictions require the waiver of rights (or a guilty plea) for defendants to participate. Coercive criminal procedure itself also risks tainting the therapeutic process; even though court personnel receive special training regarding post-traumatic stress disorder and veterans, they remain legal rather than mental health professionals and may impede treatment through well-intended but erroneous efforts to aid veterans. Further, some critics argue that veterans courts risk pathologizing veterans by reinforcing negative stereotypes. The implementation of veterans courts also gives rise to equity issues. To the extent that additional public expenditures yield improved outcomes, these courts raise questions about denying the forum to other defendants, especially those who have post-traumatic stress disorder, and who might be inclined to benefit most. Even among veterans otherwise eligible, some have charged that specialized courts tend to avoid defendants with serious offenses, opening up these courts to criticisms of *creaming*, that is, selecting clients likely to succeed and avoiding needy but more challenging cases.

VICTIM ASSISTANCE PROGRAMS AND LEGISLATION

Victim assistance programs and legislation refers to support programming developed to meet the needs of victims of crime. Often this programming is legislated in an act or other mandate. This topic is relevant to students and professionals in the fields of psychology, social work, criminal justice, sociology, and criminology because they are likely to enter into helping professions that work closely with victims. This entry is organized to first provide a brief historical understanding of victim assistance programming, important dates and events, followed by a discussion of such programming, including specific services available to victims. The relevant legislation that resulted in the development of such programming is also presented.

Brief History

Victim assistance programs have been established to provide services and assistance to victims of crime. These programs, while prominent today, are the result of the 1970s' crime victims' movement and subsequently in part from the first National Crime (Victimization) Survey (NCVS) in 1973 that revealed the *dark figure of crime*. This dark figure or hidden figure of crime is criminal victimization that occurs but is not reported to authorities. Advocates began to realize that reported crime statistics were underestimates of the true amount of crime. From this realization came a great concern for victims of crime, regardless of whether the criminal activity is reported or unreported.

In 1975, a prominent district attorney in Philadelphia, PA, established the first victims' rights week. This was the first time that victimization was viewed more as a societal problem and less as an individual problem. The weeklong activities and events were organized to provide concrete and practical ideas for serving crime victims. Today, two organizations, the National Center for Victims of Crime (NCVC) and the National Office of Victim Assistance (NOVA) under the auspices of the U.S. Department of Justice, continue this legacy by providing resource guides to ensure that victims of crime receive justice.

The crime victims' movement ignited an awareness of criminal victimization that resulted in the creation of programs that provided services based on the needs of the victims and also allowed victims a voice in the criminal justice system. Before this movement, crime victims were viewed primarily as evidence, or as witnesses, to help in the prosecution of a criminal act and oftentimes the victims had little or no role in the process. Not much attention was given to victims' injuries beyond linking those injuries to the accused. Through the efforts of victim advocates, victims began to have a greater influence and role in the criminal justice process.

In 1972, the first three victim assistance programs were established in St. Louis, MO; San Francisco, CA; and Washington, DC. Victim assistance programs are designed to assist victims in the recovery process following criminal victimization. Often victimization has lasting impacts that go beyond the crime itself and include physical injury, psychological distress, and economic loss. Crime victim services provided by these assistance programs include compensation programs, crisis intervention, counseling, advocacy, information and referral, specialized services, and offender-based services. These services address the harm associated with the crime itself and the stress resulting from criminal victimization. Restorative justice is often the goal of such programming. With emphasis placed more on the victim and community and less on the offender, restorative justice is an attempt to repair the harm done by the crime.

Victim Assistance Programming

All states have victim assistance programs and some form of crime victim compensation programs. The first compensation program was established in California in 1965. By 1970, four other states and one U.S. territory created similar programs: New York, Hawaii, Massachusetts, Maryland, and the Virgin Islands. It is difficult to estimate the cost associated with criminal victimization; however, compensation programs have been established to provide resources to victims to help defray some of the financial burden associated with the victimization. These programs are set up to provide financial resources to victims for harm incurred in a criminal victimization that cannot be covered by other sources. For example, funds are available to victims and their families to pay for expenses associated with medical, dental, and psychological services; individual and group counseling expenses; and funeral or burial costs. In addition, funds are available for missed employment and other loss of wages due to the criminal victimization. The maximum amount of compensation varies from state to state; however, all states have compensation funds or programs, and the amounts vary based on the victims' needs and the services required. States receiving any federal money to support such compensation funds must also contribute state funds to these programs.

There are two national organizations supported by the federal government that provide information about victim services: The NCVC and the NOVA. The NCVC is an advocacy and resource center for victims of crime and those who serve these victims. Victim advocates can find an array of resources on its website. The NCVC advocates for stronger rights, protections, and services for crime victims.

NOVA provides services to victims while focusing on the nature and extent of the crime. Because there are different needs and perspectives, NOVA has created specializations focused on 17 specific areas to provide victims with contacts at the local, state, and national levels. These specializations include abuse of authority, child harm, disabilities harm, domestic and family violence, domestic and family violence special populations, elder harm, financial harm, harassment and stalking, hate crimes, homicide/murder and survivors, human

trafficking, identity theft, impaired driving, Internet and electronic privacy, military-related harm, Native American and tribal harm, and sexual violence.

Arguably, the most important service provided to victims is an understanding of how the criminal justice system works. Before advocacy groups were formed, victims were often revictimized by the system. Unfamiliar with the criminal justice system, victims generally have no idea what to expect in the process nor understand how slowly the wheels of justice can turn. The criminal justice system attempts to discern the amount of shared responsibility in the criminal victimization, and by doing so, it can treat victims as if they are on trial. For example, rape victims, in particular, often find the criminal justice system, especially defense attorneys, putting their behavior on trial, attempting to shift culpability for the crime to the victim. Many rape myths or misconceptions are the focus of defense attorney's cross-examination strategies. Relying on these tactics can cause emotional pain for the victim, which is also described as secondary victimization or victim blaming that tends to marginalize the victim, making it harder for them to come forward and report the offense. Victim blaming is any attitude that shifts the blame away from the offender and puts it on the victim. Victim blaming is found in attitudes characterized by statements such as "She was drunk," "She was out late," and "She left with him." These attitudes cause additional emotional harm to victims. Without understanding how the criminal justice system operates, victims are likely to experience such secondary victimization.

Crime victim services are at the cornerstone of victim assistance programs. Early in their development, these programs were housed in prosecutors' or district attorneys' offices. Today, victim assistance programs are located in a myriad of criminal justice agencies including police departments, prosecutors' offices, courts, probation, and parole offices. This expansion of housing such programs in other areas of the criminal justice system has resulted in victims having services regardless of the disposition of the case.

To further respond to the needs of crime victims, victim-offender reconciliation programs have been established. These programs allow the offender and victim to meet with a mediator in an

effort to achieve a just resolution to the case, perhaps more satisfying than going to court, and with the emphasis on restoring the victim. Victim-offender reconciliation programs, which typically accept only cases involving minor offenses, offer an opportunity for victims and offenders to meet and perhaps bring about a better resolution for both parties. These sessions are intended to empower victims by allowing them to have a real voice in the proceedings. Moreover, the face-to-face exchanges generally result in an admission of responsibility and an apology from the offender.

Legislation

There are several key pieces of legislation that the U.S. Congress passed to help victims of crime receive compensation and assistance programming. The legislation provides an array of services for specific crimes including clearinghouse information and technical assistance, self-help support groups, and prevention and awareness strategies to address victimization. Legislation can be grouped into the following broad categories:

- **Victimization of Children:** Child Abuse and Prevention and Treatment Act (1974), Parental Kidnapping Prevention Act (1980), Missing Children's Act (1982), Missing Children's Assistance Act (1984), Children's Justice Act (1985), Victims of Child Abuse Act (1990), National Child Search Assistance Act (1990), Child Sexual Abuse Registry Act (1993), Community Notification Act (Megan's Law, 1996), Adam Walsh Child Protection and Safety Act (2006);
- **Domestic Violence:** Family Violence Prevention and Services Act (1984), Battered Women's Testimony Act (1992);
- **Drunk Driving:** Drunk Driving Prevention Act (1988). Prior to this legislation, Mothers Against Drunk Driving was established as a nonprofit organization to fight drunk driving; and
- **Violence Against Women:** Violence Against Women Act (1994).

While these specific acts provide awareness and services for victims of specific crimes, there are two pieces of legislation that are applicable to all victims of crime: the Victims of Crime Act of

1984 and the Crime Victims' Rights Act of 2004. Victims of Crime Act is a federal victim compensation account funded through the collection of fines from criminal convictions. The Department of Justice under the direction of President Ronald Reagan established a President's Task Force on Victims of Crime in 1982 to study criminal victimization. At that time, the Task Force was concerned that existing victim compensation programs were not operating as intended based on reported findings such as the general lack of awareness that such programs existed, burdensome paperwork and long wait times to receive compensation, and the fear that available resources would be depleted and that staff would be overworked. The Task Force's findings resulted in Victims of Crime Act establishing the Crime Victims' Fund.

The Crime Victims' Rights Act empowers victims of crime through a set of rights. The act entails several rights that must be provided to victims in federal criminal cases:

1. The right to be reasonably protected from the accused
2. The right to reasonable, accurate, and timely notice of any public court proceeding or any parole proceeding involving the crime or of any release or escape of the accused
3. The right not to be excluded from any such public court proceeding, unless the court, after receiving clear and convincing evidence, determines that testimony by the victim would be materially altered if the victim heard other testimony at that proceeding
4. The right to be reasonably heard at any public proceeding in the district court involving release, plea, sentencing, or any parole proceeding
5. The reasonable right to confer with the attorney for the government in the case
6. The right to full and timely restitution as provided in law
7. The right to proceedings free from unreasonable delay
8. The right to be treated with fairness and with respect for the victim's dignity and privacy

As of 2018, there is no federal Constitutional Victims' Bill of Rights. However, many state constitutions and state laws provide the rights listed in the Crime Victims' Rights Act to their residents and others victimized in their states.

VICTIMIZATION IN PRISONS

Victimization in prison refers to being the recipient of negative actions or threats of negative actions within the confines of the penal institution by persons living or working in such spaces. Such actions are either physically or psychologically harmful, and the harm can be to a person's mind, body, or something that person values (e.g., possessions or freedom). Victimization in prison is of central importance to any study of criminal psychology; it transcends disciplines and changes shape in line with penal legislation and practices. Being victimized, witnessing victimization, or engaging in the victimization of another person impacts prisoners, prison staff, and their families

and friends. Victimization has long-term consequences for victims and perpetrators, may encourage recidivism, and perhaps even desistance as once perpetrators take accountability for their actions they may become more open and able to seek new trajectories for their future growth. As such, victimization in prison is of relevance to many legal and psychological professions as well as health, social work, and justice professionals. This entry takes a look at understanding victimization in prison, examines prison hierarchy, and explains the variations, measurement, and effects of victimization in prison.

Understanding Victimization in Prison

The uncertainty of prison living—and the omnipresent vulnerabilities that shape higher security prison living in many countries—is often exacerbated by imminent and consistent threats of violence. *Violence*, here, is broadly defined to include harm or the threat of harm to an individual's body, mind, possessions, legal status, or any thing or person in which that individual places value (e.g., family, material goods inside or outside of prison) for both prisoners and prison staff alike. Both prisoners and prison staff can be the perpetrators or victims of violence or harm in prison, and victimization can take many different, creative forms. For example, a prison officer's family can be threatened in an effort to persuade him or her to bring in contraband, or a prisoner's pending parole can be threatened by forcing him or her to engage in misconduct or be physically harmed.

In the United States and Canada, 10–20% of prisoners report some level of physical victimization by other prisoners, based on 6- to 12-month exposure periods. Even so, victimization in prison is inevitably grossly underreported due to the negative connotation of *snitching* within prisoner cultures. In adult men's prisons, an inmate code is documented that suggests a prisoner must not *rat* on a fellow prisoner if he or she does not want to be harmed in consequence. In more recent iterations of the code, researchers put forth that prisoners are to be dependable, to mind their own business, act tough, and refrain from getting friendly with staff. Thus, prisoners may not snitch but, in a Canadian sample of men released from federal prison, Rose Ricciardelli found that nearly

every man interviewed had experienced some kind of victimization, and most had physical or psychological scars as a result of these experiences.

Nevertheless, very little mention is made of the psychological victimization that runs rampant in carceral spaces, presumably because of its invisibility and the reluctance of prisoners or correctional staff to admit either being a perpetrator or recipient of emotional abuse. Some have argued that admitting to psychological victimization is difficult in prison because it is a hypermasculine space and as such any admission could be considered emasculating and encourage future victimization for persons, male or female, who admit to being victims. To put it another way, someone who reveals his or her victimization may be viewed as weak.

The Prison Hierarchy

For those incarcerated, victimization in prison is also the result of the convergence of a number of complex factors such as the type of crime for which one is charged or convicted, the level of crowding in the facility, the strength of administrative controls, or the security design of the institution. A hierarchy structured largely according to each prisoner's criminal convictions, charges, and connections exists among prisoners. A prisoner whose charges are tied to robbery, theft, gun violence, murder, or other such *solid* charges is able to hold a more prestigious position in the hierarchy. On the other hand, a prisoner convicted of sex offenses occupies the lower rungs on the metaphorical ladder. In particular, the lowest rung is reserved for sex offenders whose victims are children and the position directly above is held for prisoners who sexually victimize women. Thus, where a prisoner's crime falls within this hierarchy will do much to determine his or her status in prison. A prisoner's convictions or charges can become known to other prisoners through a variety of means ranging from the local newspaper and television programming, the words of prison officers or prisoners, rumors, or even prisoners asking their connections outside of prison to Google particular prisoners to learn about their criminal history. If prisoners are being held for sex-related convictions or charges, to reduce the potential for victimization, they often serve their

time in remand or once sentenced in *protective custody* where they can be housed alongside others convicted or charged with sex-related offenses or other prisoners who require some type of segregation from the general prison population in light of their or the institution's safety being under threat.

Beyond crime, depending on the prison, other factors such as gender presentation, sexuality, and criminal affiliations can also impact where a prisoner falls in the hierarchy. Thus, someone low in the hierarchy is likely to experience harsher and more frequent victimization, for example, he or she may experience constant theft, harassment, and physical harm. Moreover, those with more status in prison are not necessarily safe from victimization. Instead, particularly in more secure men's institutions, a prisoner seeking to improve his status will seek to harm a prisoner in a superior position to prove his own abilities. Generally, the higher the status of the prisoner, the more a prisoner is feared or found to be intimidating, which are both qualities that can provide some degree of safety from victimization. In more secure institutions, however, conditions of confinement may leave prisoners feeling more vulnerable, given prisoners have expressed concerns about what other prisoners are capable of (e.g., when in for murders, torture), and the associated threat that different prisoners pose due to the frustrations and hardships tied to living in highly secured custodial spaces with few privileges (e.g., extensive hours being locked in cells). This threat creates a need for prisoners to watch their backs. Overall, prison living is mundane, yet unpredictable, and thus, any person for whatever reasons can be susceptible to victimization when incarcerated. Further, the victimization can change forms depending on the characteristics of the institutions and other prisoners.

Variations in Victimization Across Security Classification

Experiences of victimization may change form in prisons of different security classifications. Men and women in less secure institutions, such as minimum, are more at risk of being accused of engaging in misconduct and thus being transferred to a more secure institution where they would

have fewer privileges and freedoms, while prisoners in more secure institutions are often working toward being transferred to a less secure institution where violence and victimization are less pronounced. Prisoners, across institutions, do report that there is a need to keep their parole eligibility quiet in prison because their pending release can put a target on their backs as another prisoner may attempt to nullify their parole eligibility by engaging them in misconduct (i.e., altercations or something of the sort) that results in institutional charges or delayed parole. Prison atmospheres are often hostile and tense, with an underlying violent potential; understanding that what constitutes violence is wide ranging—it can be physical, psychological, emotional, legal, or in-kind—is of value as all prisoners (and prison staff) are vulnerable.

Measuring Victimization in Prison

Researchers reveal that knowledge of victimization in prison is rather underdeveloped because of the many difficulties they encounter when seeking to measure its occurrences. Indeed, any reliance on formally documented occurrences of victimization provides a skewed result that would suggest victimization is less frequent than it occurs in actuality. As such, measures that do not rely on aggregate data collected by prison staff are essential. The two most commonly used research methods to learn about, classify, or measure victimization are survey and behavioral studies. The former often relies on the self-reports of prisoner populations when asked questions specifically about their experiences of victimization in prison. Generally speaking, these studies use questionnaires that are administered on paper to prisoners and produce localized results that are difficult to generalize across different populations and prisons. For example, patterns of victimization reported may be specific to the sample surveyed because of the conditions in that particular prison or characteristics of that prisoner population. The latter, behavioral victimization studies, involves the researcher focusing on how prisoners alter their behaviors to avoid altercations and possible victimization. Avoidance behaviors include individual reports of constantly being nervous or on guard when in prison or avoiding areas perceived as *risky* (e.g.,

bathrooms, showers, or other areas outside of the security cameras' range). Research on prisoner behaviors can then be used to delineate specific patterns of victimization as they affect different prisoner populations as well as staff. Although this body of research is small, implications include providing insight into the patterns and the degree of vulnerabilities prisoners experience—how safe they do or do not feel. Such understandings may help to create safer prison spaces for prisoners and staff alike.

Effects of Victimization in Prison

Although prisoners are victimized behind prison walls, these experiences can and do negatively affect the ways prisoners and prison staff view the justice systems as well as the long-term community reentry potential of prisoners. Government and prison management and staff are collectively responsible for the safety and security of correctional facilities and all those within. The existence of victimization, either among prisoners or staff, is suggestive of inadequacies within these penal systems that result in unsafe and insecure environments, in some cases even a lack of justice. Prisoners and staff members that experience victimization, particularly when the perpetrators are neither held accountable nor acknowledged, may manifest a lack of faith in the prison system and systems of justice more generally—this is most pronounced with legal victimization. Experiences of victimization can also negatively impact a victim's self-esteem, confidence, social functioning, and psychological well-being. The combination of little faith in systems of justice and a compromised sense of self or well-being leaves victims even more prone to difficulties during prison and after incarceration during reentry.

VICTIMS OF CRIME

Crime victims are persons harmed by criminal acts, as defined by law. Although most criminal violations have identifiable victims, some crimes are considered victimless crimes; these commonly comprise transactions conducted between willing participants who are interested in the exchange and do not consider themselves victims (e.g., gambling or prostitution in states that prohibit such activities). Victims include direct or primary victims who are persons directly harmed by the criminal act; secondary victims who are commonly family and friends of direct victims, and in some cases, first responders who attended to direct victims; and tertiary victims who are those exposed to the harm indirectly (e.g., as through media communications). Victimization includes physical, sexual, psychological, and financial harm, experienced in person, indirectly, or via the Internet. Since many victims have to go through the criminal justice process while their violator has his or her day in court, an important aspect of the victimization experience is related to victim participation in criminal justice proceedings and encounters with the system's agents, including police, prosecution, judges, and parole staff in regard to an offender's request for early release. This entry addresses the history of the study of victims, types of victimization and their effects on victims, and the role of victims in the criminal justice system.

History of the Study of Crime Victims

Until the 1970s, victims in adversarial criminal justice systems in countries such as the United States, Canada, the United Kingdom, or Australia have been invisible. Issues of victims and victimization were also ignored in research and scholarship until that time. The role of victims in crimes was first given attention in 1947, when Benjamin Mendelson coined the term *victimology* and classified victims according to their contribution to the law violation, from being totally innocent to totally responsible. Soon thereafter, Hans von Hentig authored *The Criminal and His Victim* (1948), and examined proneness for victimization, classifying persons according to their vulnerability

for becoming victims (e.g., the young, immigrants, those with developmental disorders). In 1957, Marvin Wolfgang published *Patterns in Criminal Homicide*, in which he identified the phenomenon of victim-precipitated homicide. He demonstrated that in over one quarter of the homicide cases in Philadelphia, the victim initiated the use of violence or a weapon. Wolfgang concluded that in such circumstances who becomes a victim and who is an offender is a random event. Menachim Amir's *Patterns in Forcible Rape* (1960) was a controversial study of rape that adopted Wolfgang's framework; his suggestion that rape victims may precipitate their victimization was highly criticized. Other studies that featured this framework included André Normandeau's 1968 work "Patterns in Robbery."

The study of victims initially focused on the ways victims shape their offender or contribute to their victimization. In later years, with the impetus from the President's Commission on Law Enforcement and Administration of Justice (1967), issues such as reporting crime to authorities, victims' motives to report victimization, and police responses to crime and victims were noted. The concept of *dark figure* crime (i.e., crime that remains unknown since victims do not report their victimization) began to be the subject of research. Victimization surveys (i.e., research that measures victimization by surveying the general population about their victimization and whether it was reported to the police) were offered to rectify the validity of official statistics and adjust the size of the crime phenomenon as it appeared in official statistics. In the 1970s, activities by the women's movement called attention to victims of domestic violence and sexual assault, leading to legislation that addressed violence against women, including new offenses such as stalking, family violence, and sexual harassment. With the emergence of the Crime Victims' Rights Movement in the 1980s, attention was directed to the criminal justice system's mistreatment of victims resulting in victim alienation and dissatisfaction with justice proceedings. The movement's activities led to reforms which resulted in various victims' rights, including notification and right to be present in proceedings, compensation and restitution, safety from intimidation, speedy trial, and rights to participate in proceedings and provide decision-making input.

Today victimology is considered an area that complements criminology (i.e., the study of crime and criminals), addressing questions pertaining to victims, victimization, and the role of victims in justice proceedings. The field is interdisciplinary, incorporating insights from the various social sciences, including anthropology, sociology, psychology, economics, political sciences, socio-legal studies, as well as public health, psychiatry, and medicine.

Types of Victimization and Their Effects on Victims

Victimization takes many forms; regardless of the type of violation, there are commonalities in the ways victims experience and respond to victimization. There are also unique victims' responses, dependent on the offense type and circumstances, victim personal attributes, and history of victimization. Research has also addressed patterns of reporting behavior and motives to report victimization. Common reasons for which victims do not report include: victim belief that the victimization is not important enough to report, that the police cannot do anything about it; fear of retaliation by the offender; the victim has dealt with it in another manner; and combinations of these reasons; the frequency of each reason may differ according to offense type. This section discusses the most common types of victimization, according to official statistics and national victimization surveys. With the advancement of technology, victimization now occurs in virtual spaces, new types of victimizations have emerged, and traditional offenses that were once only perpetrated in person now take place in cyberspace (e.g., stalking, harassment, threats, fraud).

Sexual Violence

Victims of all ages experience sexual violations that range from molestation (i.e., sexual contact), harassment, stalking (i.e., repeated pattern of unwanted attention) to sexual assaults or rapes—the latter being the most serious form of sexual violence. Both females and males can be the victims of sexual assault, although the majority of rape victims are females, between the ages of 16 and 35 years. Rape myths about women (e.g.,

when women say no they do not mean it; if women drink alcohol, dress, or behave in a certain way, they are *asking for* sexual contact) have contributed to their victimization. Underage persons (i.e., younger than 18 years) are often sexually assaulted by persons familiar to them—relatives, family friends, neighbors, and parents. Children, often as young as 8 years of age, are being trafficked for pornography and commercial sex, to meet the demand that some people and pedophiles have for young partners. Sexual assaults result in severe mental trauma for victims, particularly children. Short- and long-term effects include nightmares, post-traumatic stress disorder, depression, anxiety, distrust of others, difficulties in having normal sexual relations as adults, and in some cases, suicide. Rape in marriage is a common form of domestic violence, which is currently criminalized in all states in the United States.

Victims and Survivors of Homicide

Persons of all ages are victims of homicide. Killing can be planned (i.e., murder) or unintentional (i.e., manslaughter), accidental, or occur in the process of committing other crimes. Women are more often killed by intimate partners than by strangers. Men are often killed by other men; gang- and organized-crime-related homicide commonly involve men as victims, although missed hits or random shooting may take the lives of innocent bystanders of all gender categories and ages. Survivors of homicide victims, the family members, and friends of victims who were murdered or killed are considered the indirect victims of homicide; they go through a long, difficult grieving process. Research has shown that they experience post-traumatic stress disorder, the level of which depends on survivors' degree of resilience, social network support, and events that follow the death (e.g., having to move, change schools). Research also suggests that survivors commonly claim that closure is never reached and constant reminders (e.g., empty chair at the table; birthdays of the murder victim) bring back memories and cause sadness, making it difficult to forget. Death due to homicide (compared to death resulting from illness or due to natural disaster) is also associated with the criminal justice proceedings of the perpetrator, which many include a

defense attorney blaming the victim, tarnishing the victim's reputation, or denying the perpetrator's responsibility; media attention to the case; and disturbing broadcasting of the case details and proceedings. All of these have the potential to cause survivors additional stress and grief.

Domestic Violence and Related Offenses

Violence against family members (i.e., abuse or violence against present or past spouses, intimate partners, children, parents, in-laws) or those who share the same household (i.e., roommates) is defined as domestic violence. Child abuse and elder abuse include mistreatment of minors and the elderly that consists of physical, sexual, and/or emotional victimization, as well as neglect, often perpetrated by family members or other caretakers. Much of the research has been conducted on intimate partner (i.e., married, co-habituating, or ex-partner) violence. It includes physical, sexual, financial, or emotional abuse and at times includes victimization of an abused partner's children or pets.

Domestic violence is characterized by control and domination of the victim; the battering is often unpredictable and can be triggered by the victim's action or behavior. An abuser tends to isolate victims, belittle them, destroy their self-image, and convey the idea that they cannot live or manage on their own, increasing their dependence on the abuser. Victims often do not report abuse to authorities for a long time, as they attempt to satisfy the demands of their abuser, hoping he or she will change.

Victims are often emotionally and economically dependent on the abuser, making it harder to leave, particularly if they have children together. Victims also do not leave for fear of retaliation; research shows that victims are at heightened risk when they try to separate from their abuser, a phenomenon known as *separation assault*. Stalking (i.e., patterns of behavior aimed at initiating another person) is also associated with attempted separation from an abusive intimate partner.

Immigrant women are particularly vulnerable to abuse, as they often are, or believe they are, dependent on their abuser, since the abuser often uses immigration papers as a weapon to compel the wife (or girlfriend) to conform to the abuser's

demands, threatening the loss of immigrant status or reporting the wife (or girlfriend) to authorities. Abused women may also fear that if they report the battering the abuser (commonly the husband or boyfriend) will be deported, and these women will lose their source of support or their immigration status.

The high prevalence and incidence of domestic violence victimization has been associated with high costs to society in terms of medical expenses, lost working days for the victims, and most importantly, negative impact on children who grow up in abusive homes. Many countries and states have passed domestic violence laws, which in some cases mandate the arrest of batterers as well as provide for various services to victims (e.g., counseling, shelters, compensation).

Property Crime

Property crime is the most frequent type of victimization. It includes various forms of misappropriation of property, such as theft, burglary, or robbery (the latter has also elements of violent crime, due to the perpetrator's hostile face-to-face encounter with the victim, which is normally absent in burglary). Victims of property crime experience stress and anxiety due to the loss of material goods or money, and in some cases experience severe trauma. Those victimized by burglary report trauma related to their home intrusion and violation of privacy; they also fear that the perpetrator may return, particularly if they report the crime. Victims of robbery experience serious trauma as the crime is commonly perpetrated with a weapon or threats to use a weapon if the victims do not comply with the demand to surrender their valuables or money. Victims of property crimes such as theft or burglary often do not report their victimization because they do not believe the police can do anything about it. Victims tend to report when an insurance claim is involved and reporting to the police is required (e.g., in cases of auto theft).

Financial Crime

Persons of all ages are victims of financial crimes, although the elderly experience financial abuse more often than other age groups. Financial crime

takes various forms, including telemarketing, mortgage fraud, mass marketing (domestic and international), phishing, and Ponzi schemes, often appearing as affinity fraud whose target victims are in-group members (e.g., immigrants of a specific ethnicity, religious and minority groups, the military). Identity theft is also associated with loss of money, and its victims go through a long, debilitating process of proving they were victims of fraud and restoring their credit. Victims of financial crimes are often too embarrassed to report the victimization, as they are concerned with being viewed as greedy, stupid, or otherwise responsible for their own victimization. Financial abuse is often perpetrated by family members, caretakers, or persons working in residential facilities who have access to or control over the finances of dependent elderly residents. Dependent persons often rely on family members or caretakers for their survival or comfort and thus are particularly vulnerable to financial abuse. These victims are not likely to report the victimization for fear that they would lose the support and help of their caretakers, on whom they are highly dependent.

Role of Victims in the Criminal Justice System

The role of victims in a criminal justice proceedings of adversarial legal systems (e.g., the U.S. legal system) has changed dramatically over the centuries—from a system in which victims were expected to deal with offenders directly, to one in which the state now assumes the duty of bringing offenders to justice. Because in adversarial systems, the parties to proceedings are the state and the accused, victims do not have a party status; at best, they serve as witnesses at the trial of their violators. For most victims, even their role as a witness will not always materialize, due to the high attrition of cases that reach the criminal justice system, as well as high rates of negotiated pleas between the prosecution and the defense. Consequently, until the 1970s, crime victims have been neglected by the criminal justice system, feeling forgotten, alienated, and dissatisfied with justice. During the 1970s and 1980s?, with the emergence of social movements that addressed women's concerns (e.g., sexual

assault and other forms of violence against women, and Mothers Against Drunk Driving) and the concerns of victims in general, the treatment of victims in justice proceedings began to attract attention. Victims are now accorded various privileges and rights, including notification about proceedings, right to be present in proceedings, the right to receive restitution from the offender or compensation from the state, the right to a speedy trial, and most importantly, the right to be consulted and provide input into criminal justice decision-making regarding the person who violated them. Victim input may apply to issues such as charges filed, bail requested, plea bargain specifics, sentencing (by means of a victim impact statement), and whether a convicted offender is released on parole. Although currently there are no legal sanctions for nonenforcement of these rights, they nonetheless signify an important step in the criminal justice approach to victims, viewing victims as insiders rather than outsiders and as important participants in justice proceedings.

Violence Against Children

Many misconceptions exist about violence against children. When thinking of *violence*, many people may think about physical harm or child abuse. However, violence against children not only involves the intentional harming of a child or adolescent but also includes mental anguish and neglect. Furthermore, violence does not only occur

in the home at the hands of parents or guardians and does not always result in the child being removed from the home and placed into a safer environment. This entry addresses the types of violence against children, where child violence occurs, who commits child violence, and the effects of violence on children.

Types of Violence Against Children

Violence against children is not uncommon. An estimated 1 billion children are victimized worldwide every year. Violence against children can take many different forms, including the following:

Physical violence against a child is recognized as an act of using an object (e.g., a belt) or a part of one's body (e.g., an open hand or a foot) as a way of controlling a child through physical force that results in pain or physical injury. Examples of physical violence include, but are not limited to, hitting, hair-pulling, beating, kicking, force-feeding, deliberately exposing a child to severe weather or harsh temperatures, and murder. Within physical violence, medication abuse can occur. This happens when a caretaker withholds necessary medication, does not comply with prescription instructions, or either over- or undermedicates the child. Another subset of physical violence is known as *restraints abuse*. Restraints abuse occurs when a child is forcibly confined to a room such as a closet or a basement or is forcibly confined to an object such as a bed or a chair via physical restraints. Similarly, giving a child unnecessary medication as a means of control is considered restraints abuse (e.g., administering a sedative or an antihistamine on a regular basis for sedation).

Sexual violence against a child occurs when a child is forced into a sexual act, such as rape or molestation (i.e., kissing and fondling). However, sexual violence can also occur in instances such as forcing the child to take part in or watch pornographic material, beating the child's sexual genitalia, or forcing the child into prostitution. Generally, children cannot legally consent to having sexual relations with an adult. The age of consent for sexual relations varies throughout the United States and the world, and *consensual sex* between an adult and an adolescent may be legal, depending on the state or country, age of the adolescent, and age of the adult.

Emotional violence against a child occurs when mental pain is intentionally inflicted as a means to control the child with feelings of worthlessness. Such violence occurs through acts such as name calling, telling a child that he or she should not have been born, and teasing, humiliating, and degrading the child.

Psychological violence is the use of threats, both verbal and physical, to instill fear in the child to gain control. This violence consists of threats of violence, verbal aggression, isolation (i.e., not allowing the child to interact with friends and keeping the child out of school), destroying items that the child is fond of (i.e., burning a favored toy or killing a pet), and treating the child as a servant. Psychological violence can also occur when a child is directly exposed to violence against someone else, including witnessing domestic violence perpetrated against a parent or caregiver.

Spiritual or religious violence is recognized as using a child's spiritual or religious beliefs in a negative way to gain control, such as mocking and demeaning the child's beliefs or manipulating beliefs to make the child comply with another person's demands. An example would be a clergy member justifying molesting a child by saying that God wanted it to occur.

Cultural violence takes place when the culture, religion, or tradition in which a child is being raised inflicts harm as a result of its rituals or practices. For example, some cultures allow female circumcision, sexual slavery, and child brides.

Verbal abuse is recognized as a separate form of abuse to describe emotional abuse, along with threats, which are typically considered psychological abuse.

Neglect is recognized as a caregiver failing to provide the care or assistance needed by the child. Physical neglect occurs when items such as food, water, shelter, clothing, and friendship are either withheld or inadequate. Medical neglect occurs when the special dietary or medication needs of a child are either withheld or are not adequately met.

The types of violence against children can usually be divided into four categories: self-directed violence, interpersonal violence, corporal or physical punishment, and humiliating or degrading punishment. It is important to remember that the

types of violence against children often overlap with each other and rarely occur singularly. Although not necessarily violence against a child, *self-directed violence* occurs when a child self-mutilates (e.g., cutting, hair pulling) or attempts to commit or successfully commits suicide. Children often commit acts of self-directed violence after being victimized. *Interpersonal violence* encompasses typical forms of abuse (i.e., physical, sexual, and psychological abuse, as well as neglect). *Corporal punishment* is physical abuse, including but not limited to hitting, shaking, and burning the child. *Humiliating or degrading punishment* encompasses verbal abuse, emotional abuse, and psychological abuse.

Where Does Violence Against Children Occur?

Violence against children occurs in places that are obvious, such as the home, but it can also occur in places that are typically thought of as safe for children, such as daycare or a foster home. A landmark 2006 study conducted by the United Nations found that violence against children is widespread, occurring across the world, in every society, and in every culture. However, the violence often occurs in settings that allow for easy access to a child and little-to-no detection of the violence occurring.

In the Home

While it seems ironic, children are at the greatest risk of becoming victims of violence in their homes, with the most vulnerable being younger children. For example, children who become victims of sexual abuse most often know their attacker, who is often a member of their family or a family friend. With regard to physical abuse in the home, in 2012, approximately 60% of children between the ages of 2 and 14 worldwide experienced regular physical punishment by their caregivers, and it is well known that when used harshly, discipline can cross the line from correction to violence.

In Schools and Educational Settings

Children often fall victim to violence in schools. Children are most often exposed to

psychological violence in school, through humiliation, degradation, and insulting comments made by teachers or school officials. Bullying is also considered a form of violence against children and is most often seen in or near the school grounds.

In Care of the State and Justice Systems

Determining the total number of children in the care of the state and justice system around the world is currently impossible because of lack of record keeping. Estimates from the early 1990s indicate between 6 and 8 million children throughout the world were living in some form of governmental or nongovernmental residential care; in 2007, the United Nations International Children's Emergency Fund estimated that 1 million children were detained in some sort of justice system worldwide at any given time. Violence against children in these settings occurs at the hands of individuals responsible for their well-being as well as other children. Not infrequently, medication abuse occurs as a means to make a child more *compliant* or manageable.

In Work Settings

Violence against children in the workplace typically occurs in countries where children work, whether legally or illegally, where few to no child labor laws exist. The abuse can occur in the form of coercion or punishment or in violation of existing child labor laws. The majority of the violence is inflicted at the hands of the employer; however, coworkers, supervisors, and customers can also be offenders.

In the Community

The community is most often where children become victims of peer, gang, and police violence as well as nonfamilial sexual violence and trafficking. However, community violence rarely affects children at random, rather, targeting children who spend a great deal of time on the streets. A more recent type of community violence is cyberbullying. While it has existed since the beginning of the Internet, cyberbullying was first prohibited by law in Colorado in 2005.

Who Commits Violence Against Children?

Violence against children occurs in almost every setting, so it is likely not surprising that it can be committed at the hands of almost anyone. Perpetrators of violence against children are not isolated to a specific gender, race, religion, or socioeconomic class. Although it is not uncommon for peers and strangers to prey on children, the typical offenders are individuals in a position of power (i.e., parents, caregivers, teachers, and police officers). Most of the research on individuals who commit violence against children focuses on the typology of male sex offenders.

Effects of Violence on Child Victims

The effects of being a victim of childhood violence generally vary according to the severity of the violence. However, no matter the severity of the offense, the ramifications of the violence can still be detrimental to the health, well-being, and development of a child. As a result of violence, children can experience a myriad of emotional difficulties, which can continue into adulthood (e.g., depressive disorders, traumatic stress disorders, anxiety disorders). Up to 80% of childhood violence victims meet diagnostic criteria for at least one psychological disorder as adults.

Child victims can also experience medical problems and stunted development, with extreme cases leading to death. For example, child victims of violence can experience maladies such as brain injuries, failure to thrive, nutritional deprivation, sexually transmitted diseases, scarring, and intellectual disabilities. In fact, over a quarter of children who were victimized have chronic health conditions.

Furthermore, children who are victims of violence are at greater risk of becoming violent toward themselves and others in the future. Due to their exposure to violence, children are taught that violence is an acceptable and appropriate way to cope with problems and to deal with others, and this impacts their psychosocial functioning. For example, individuals who are victimized as children are 30% more likely to be involved in violent crime as an adult. Similarly, 68% of incarcerated adult male felons reported experiencing some type of victimization before the age of

12 years. Moreover, childhood victims of violence may turn their aggression inward. For example, close to a third of children who have been sexually abused attempt suicide. Finally, children who are victims of violence are susceptible to developing behavioral problems (e.g., substance misuse and promiscuity). More than two thirds of people in treatment for substance misuse were maltreated as a child. Similarly, individuals who are victimized as children are less likely to practice safe sex, putting them at greater risk of sexually transmitted diseases.

VIOLENCE RISK APPRAISAL GUIDE (VRAG) AND THE VIOLENCE RISK APPRAISAL GUIDE–REVISED (VRAG-R)

The VRAG and the VRAG-R are actuarial instruments designed to estimate the likelihood with which a male criminal offender or forensic psychiatric patient will be charged for at least one new violent offense within a 7- or 10-year period of opportunity to reoffend. Opportunity to reoffend is defined by community access, and violent offending is defined to include hands-on sex offenses. An actuarial instrument derives a probability of a future event's occurrence by tabulating the frequency with which the event has occurred in the past among individuals from a similar population.

Many decisions about offenders in the criminal justice and forensic psychiatric systems are dependent on formal or implicit appraisals of risk—most importantly, in terms of community safety, the risk of an offender committing new violent or sexual offenses. Risk appraisal is therefore relevant to granting bail, sentence length, amount of supervision on parole and probation, release to the community, and assignment to institutions varying in level of security. As with a number of actuarial instruments, the VRAG and the VRAG-R were designed to assist in the determination of the degree of risk posed by individual offenders.

The VRAG

In the case of the VRAG, offenders were followed after release from incarceration and the frequency with which they committed additional violent or sexual crimes was noted. Prerelease characteristics of these offenders were then related to whether they had committed a new violent or sexual

offense. The characteristics that were most highly related to recidivism were combined to yield a single score that could be used to estimate the probability of violent/sexual reoffending in new cases.

VRAG Items

The VRAG comprises the following items:

1. Revised Psychopathy Checklist score (a rating instrument devised by Robert Hare to measure psychopathic personality traits such as callousness and duplicity)
2. Elementary School Maladjustment score
3. meets psychiatric criteria for any personality disorder
4. age at time of the index offense (negatively related to recidivism)—the index offense is the offense leading to institutionalization or referral
5. separation from either parent (except death) under age 16 years
6. failure on prior conditional release
7. nonviolent offense history
8. never married (or equivalent)
9. meets psychiatric criteria for schizophrenia (negatively related to recidivism)
10. most serious victim injury in index offense (negatively related to recidivism)
11. alcohol abuse score
12. female victim in index offense (negatively related to recidivism)

The items were selected from a larger pool based on their relationship to violent recidivism rather than on theoretical or commonsensical ideas, so they may seem counterintuitive. The negative relationship between schizophrenia and violence risk is an exemplar of such an apparently anomalous result. The reason for this negative relationship becomes apparent on reflection: In studies of the general population, schizophrenia and other major mental disorders are modest risk indicators but are much poorer risk indicators

than diagnoses of personality disorder, sexual deviance, and substance abuse. Thus, when a sample of offenders is studied, schizophrenia appears to be a protective factor because those with schizophrenia are being compared to a group composed largely of offenders who are personality disordered, paraphilic, and/or substance abusing. Similar considerations apply to some of the other items. Murderers have, on average, lower rates of violent recidivism than a group of unselected offenders; offenders who have female victims do not contain homosexual pedophiles (who have high rates of sexual recidivism). Part of the issue with both murderers and offenders with female victims is that a substantial proportion of both groups committed their admission offense against their spouse and such individuals tend to have low rates of violent recidivism.

Some readers may point to exceptions to the assertions in the preceding paragraph, such as domestic murderers who turned out to be serial killers or serial rapists (of women). Two considerations temper the force of these objections. The first (and weaker) is that the instrument deals in probabilities not certainties. Second, and more importantly, the items work together, rather than in isolation. It is the combination of items (e.g., a pattern of early antisocial behavior coupled with an adult offense) that yields a high-risk score. The VRAG is in part a measure of the persistence of antisocial and criminal behavior across the life span. In the end, however, it is not theoretical ideas, commonsense notions, or anecdotes derived from one's personal experience or reading that count but only the empirical relationship between the actuarial measure and outcome.

Principal Results

Data from the original sample of 618 offenders are shown in Figure 1. Each offender had been assessed or treated at a maximum-security psychiatric facility in Ontario, Canada; most of the assessed-only offenders were subsequently sentenced to correctional facilities before their release. VRAG scores are divided into nine equal-sized ranges (bins), and the probability of violent recidivism is shown by the height of the bar for each bin. The line denotes the number of offenders in each bin. Figure 1 shows the linear relationship

Figure 1 Probability of violent recidivism as a function of the score on the Violence Risk Appraisal Guide (VRAG).

Source: Quinsey, V. L., Harris, G. T., Rice, M. E., & Cormier, C. (1998). *Violent offenders: Appraising and managing risk* (2nd ed., p. 148). Washington, DC: American Psychological Association.

between VRAG score and the likelihood of violent reoffending and that relatively few individuals receive very high or low scores.

Accuracy of Prediction

The measurement of predictive accuracy is complex and has sometimes been controversial, although in 2015, there is a consensus among statisticians about what methods should be used and how the results of these should be interpreted. Actuarial methods are used for prediction and evaluated similarly in many areas, such as medicine and the insurance industry. One simple way of indexing predictive accuracy is to calculate the likelihood that a randomly sampled individual from one outcome group (in this case, violent recidivists) will have a higher score on a predictive instrument than a randomly sampled individual from the other group (those not committing such offenses). This probability in the case of the VRAG is approximately .75, indicating sufficient accuracy to be useful in practical decision-making about release and supervision for individual offenders. It is important to understand that an actuarial instrument (or any other method of prediction) is less useful when applied to a population in which the base rate of the phenomenon to

be predicted is very high or very low. This would occur in the case of the VRAG where almost all or almost no offenders in a particular population committed new violent offenses. Thirty-one percentage of offenders in the original sample were violent recidivists in 7 years at risk.

The accuracy of the VRAG compares favorably with other methods of predicting violent reoffending. It has long been known that mental health professionals, including experienced forensic psychologists and psychiatrists, show poor agreement among themselves in predicting violent recidivism, overpredict its occurrence, and are less accurate than actuarial instruments. The accuracy of clinicians can be improved by structuring their judgment with standardized rating scales or checklists, although research indicates it usually falls short of that obtained with actuarial instruments such as the VRAG. Neither professional judgment nor structured discretion methods yield an actual probability of violent reoffending. However, the absolute probability of reoffending is not critical for all types of decisions. For example, forensic or correctional administrators may have fixed budgets for treatment or supervision and may wish to differentially provide these to higher risk cases. Relative risk, as indexed by the percentile rank of the offender on the VRAG, is appropriate for this type of decision.

Replications

Since the VRAG was introduced in the 1990s, there have been about 60 replications around the world, most of which were conducted by individuals unconnected with the VRAG authors. The VRAG, like most actuarial instruments, is robust upon replication: For example, accuracy in predicting violent recidivism in the community in six studies conducted by the VRAG authors averaged .73 and averaged .72 in 20 replications conducted by others.

The VRAG-R

The VRAG-R, first published in 2013, was developed primarily to simplify the VRAG scoring system. The VRAG-R correlates highly with the VRAG and has nearly identical accuracy of prediction. Because the VRAG-R is easier to score,

the developers of the VRAG and VRAG-R recommend use of the latter.

The sample of 1,261 offenders used for its construction included the offenders used to develop the VRAG. The VRAG-R has 12 items, each scored or weighted according to the direction and magnitude of its relationship to violent (including sexual) reoffending, and then summed to obtain a total score. The items are historical (static) in nature and do not change with time, unless there is a new offense and the offender is reassessed.

VRAG-R Items

The VRAG-R items comprise the following:

1. lived with both biological parents to age 16 years (negatively related to recidivism)
2. elementary school maladjustment
3. history of alcohol or drug problems
4. marital status at time of index offense
5. charges for nonviolent offenses prior to index offense
6. failure on conditional release from corrections
7. age at index offense (negatively related to recidivism)
8. charges for violent offenses before index offense
9. number of prior admissions to correctional institutions
10. conduct disorder before age 15 years
11. sex offending
12. antisociality: poor behavioral controls, early behavioral problems, juvenile delinquency, revocation of conditional release, criminal versatility

The items are designed to be scored from information contained in the offender's file: a detailed psychosocial history or parole/probation assessment, psychological and psychiatric assessments, court records, criminal history, and psychiatric history. Given adequate information, it is not necessary for the assessor to interview the offender to

complete the assessment. To the degree possible, information from multiple sources is used. It is particularly important for assessors to corroborate information obtained from offender self-report. When there is missing information for a particular item, it can be prorated (estimated) according to a formula. Up to 4 items can be prorated to obtain a valid score. Trained raters show extremely close agreement when independently scoring the same file.

The Nature of Static Risk

The VRAG-R is designed to predict the occurrence of at least one violent reoffense in a lengthy period of opportunity. Intervals of opportunity ranging from 6 months to 49 years have been examined and the VRAG-R performs well in all of them. The predictions in all cases were made at the time the offender was assessed subsequent to the commission of the index offense, thus changes in the offender that may have occurred during institutionalization or post-release were not considered. It is the case, however, that offenders are slightly less likely to reoffend with each year of opportunity to reoffend they complete without reoffending. There is a formula to compute this reduction in risk. Time spent in forensic or correctional institutions after assessment, however, does not reduce risk.

Theoretical Interpretation

The principal implication of the results of the research leading to the development of the VRAG-R is the concrete demonstration of the large variation in risk of violent reoffending posed by different offenders.

The VRAG-R items are individual-level correlates of crime, most of which have been extensively documented in many societies throughout the world. They are part of a larger class of variables sometimes termed *universal correlates of crime*. Individual correlates are distinguished from aggregate correlations. Aggregate data are collected at the country, region, or census tract level—for example, one can compare the overall crime rates among different countries or correlate the association between income disparity and crime in a particular jurisdiction. Correlations

based on aggregate data are often different than correlations based on individual data. There is, for example, a strong association between poverty and crime at the aggregate level but a weak association between poverty and crime at the level of individuals. This particular difference may exist simply because most poor people do not commit crimes, although other factors also contribute. Knowing an offender's socioeconomic status, therefore, does not help one in forecasting the likelihood of a particular offender's recidivism.

The items of the VRAG-R were selected empirically based on their success in predicting violent recidivism, not for theoretical reasons, and therefore do not in themselves constitute a theory of violent offending. The success of the instrument, a result of the lawfulness of violent offending, does have theoretical relevance; however, in that, it constitutes data to be explained by a successful theory.

The Future

The developers of the VRAG-R and most other actuarial methods designed to predict recidivism of various kinds hope that their instruments will become obsolete with the development of more effective interventions. With a perfectly effective intervention, the only information pertaining to risk a decision maker would need is knowledge of whether the offender received the intervention. More realistically, if a particular intervention had been shown to reduce the likelihood of violent reoffending by a certain amount, that amount could be incorporated into the actuarial estimate of risk via a simple formula. Alternatively, a measure of response to intervention could be developed that could be used in similar fashion. At present, this desired objective has not yet been met. Although there are some treatments or interventions for offenders that have been shown to reduce criminal recidivism, none demonstrate convincingly that the likelihood of violent or sexual reoffending among high-risk adult offenders can be reduced to the extent that it need be reflected in an actuarial prediction method.

A great deal of program development work and rigorous evaluation will be required before the

receipt of or response to intervention can be used to modify actuarial estimates of risk.

VIOLENCE RISK SCALE (VRS)

The VRS, developed by Stephen Wong and Audrey Gordon, is a forensic risk assessment tool designed to assess the risk of violence, identify treatment targets for violence reduction treatment, assess an individual's readiness for treatment, and evaluate treatment progress and posttreatment level of risk. Forensic risk assessments are widely used in clinical, forensic, and correctional practices and offender management. The VRS has been referred to as a *treatment-friendly risk assessment tool* because, unlike tools with only historic or static predictors that are not amenable to change, the VRS uses dynamic risk predictors that can change with time or treatment. Thus, the VRS integrates the tasks of violence risk assessment and treatment guidance within the same tool. This entry describes the structure and organization of the VRS including its application to different forensic populations together with supporting research evidence.

Using Static and Dynamic Predictors to Assess Change in Risk

To predict risk of violent reoffending, the VRS uses six static and 20 dynamic predictors (Table 1) that are empirically or theoretically linked to violence or reoffending. The predictors were derived from the widely used Risk-Need-Responsivity principles and an extensive review of the risk assessment and treatment literature.

Detailed descriptions of the static and dynamic predictors and rating instructions are provided in the VRS manual. The VRS dynamic and static

Table 1 VRS Static and Dynamic Predictors and Descriptions

<i>Static Predictors</i>	
S1	Current age: Age at assessment
S2	Age at first violent conviction: Age at first formal conviction of a violent offense
S3	Number of young offender convictions: Number of formal convictions before the age of majority
S4	Violence throughout life span: Overall pattern of violent behaviors up to the time of assessment
S5	Prior release failures: Violation of conditional releases (e.g., parole, probation) prior to assessment
S6	Stability of family upbringing: Assesses early family influence on personal development
<i>Dynamic Predictors</i>	
D1	Violent lifestyle: Assesses the link of the person's interpersonal, social, and overall lifestyle and violence
D2	Criminal personality: Assesses the presence of certain psychopathic personality features
D3	Criminal attitudes: Assesses the link of attitudes favoring criminal and antisocial acts and violence
D4	Work ethic: Assesses the link of the attitude toward work and violence
D5	Criminal peers: Assesses the link of peer influences and violence
D6	Interpersonal aggression: Assesses the link of interpersonal style and violence
D7	Emotional control: Assesses the link of emotional regulation and violence
D8	Violence during institutionalization: Assesses the prevalence of violence in custodial settings
D9	Weapon use: Assesses the link of weapon use and violence
D10	Insight into violence: Assesses the person's understanding of the precipitating factors of violence
D11	Mental disorder: Assesses the link of mental illness and violence
D12	Substance abuse: Assesses the link of substance use and violence
D13	Stability of relationships: Assesses the link of the stability of spousal relationships and violence
D14	Community support: Assesses the presence of supportive community resources
D15	Release to high-risk situations: Assesses the likelihood of returning to high-risk situations linked to violence
D16	Violence cycle: Assesses the presence of repeat patterns of violent behaviors
D17	Impulsivity: Assesses the presence of impulsive behaviors
D18	Cognitive distortions: Assesses the link of distorted thinking patterns and violence
D19	Compliance with community supervision: Assesses the link of supervision compliance and violence
D20	Security level at release: Assesses the security level of the person's custodial environment

predictors are rated on a 4-point scale (0, 1, 2, or 3); higher ratings (2 or 3) indicate the predictors in question are closely linked to violence in the person's overall functioning. According to the Need principle, dynamic VRS predictors (e.g., *substance abuse*) rated 2 or 3 that are closely linked to violence should be considered as the person's treatment targets or criminogenic need areas. The likelihood of future violence could be reduced by providing suitable treatment to the person's profile of criminogenic needs (i.e., all dynamic predictors rated 2 or 3) according to the Risk-Need-Responsivity principles. Risk predictors rated 1 represent *low-risk areas*, and predictors rated 0 are considered *areas of strength*. The VRS total score, which is the sum of the static and dynamic predictors ratings, indicates the person's overall level of violence risk; the higher the score, the higher the risk. According to the Risk principle, higher VRS scorers are more likely to recidivate than lower VRS scorers and should be provided with more intensive intervention. A clinical override, for example, when a high-risk individual is deemed to be at low risk because of a serious physical disability, is also provided to accommodate exceptional situations not captured by the VRS risk predictors.

Measuring Treatment Change and Change in Risk

The VRS change rubric uses a modified stages of change (SOC) model to assess the person's treatment readiness and changes in risk during treatment based on a variation of the work of James Prochaska and colleagues. The SOC model, supported by extensive research evidence, posits that treatment improvements tend to progress through a number of stages: the precontemplation, contemplation, preparation, action, and maintenance stages. The precontemplation stage is characterized by denial and refusal to acknowledge problems. The contemplation stage is characterized by acknowledging the problems, but no action is taken to change—only talking the talk. Preparation is the contemplation stage plus taking small steps to make relevant change. Action is acknowledging problems plus taking consistent action to make relevant changes. The

maintenance stage is the action stage coupled with successfully generalizing changes to many different situations. Changes are relevant if they are expected to reduce the risk of reoffending. For example, if the person has a substance use problem but, for this person, substance use has not been linked at all to offending, treatment of substance use, though beneficial, will not be risk reducing, and refraining from using substances is not a relevant change for risk reduction. The VRS provides operational descriptions for each stage to inform treatment providers what risk behaviors and change behaviors to look for during treatment. Progression from one stage to a subsequent stage is an indication of treatment improvements.

Progression from any one stage to the next stage can be translated into a 0.5-point reduction in the pretreatment risk rating; progression through two stages, a 1-point reduction; and progression through three stages, the maximum progression, a 1.5 reduction. No risk reduction is recorded for progress from the precontemplation to the contemplation stage since no behavioral improvement has taken place, only verbal acknowledgment of problems. For every dynamic risk predictor targeted for treatment, the pretreatment risk rating minus the change score is the posttreatment risk rating for that dynamic predictor. The posttreatment risk is the posttreatment dynamic total score plus the static total score; the latter, in most cases, should remain unchanged. Administration of the VRS is detailed in the VRS manual.

Matching Treatment Strategy to SOC

According to the SOC model, treatment is most effective when it matches the person's stage of change or readiness for treatment. Assessment of SOC can inform the therapist's choice of the preferred treatment approach. For someone denying any problems (precontemplation), motivational work and building therapeutic alliances are critical. Actively supporting change and maintaining motivation are particularly important during the preparation stage. Those in the action stage can be provided with increasingly more opportunities to practice their newly learned skills.

Applications to Different Populations

The VRS has been applied to many offenders/service users groups in criminal justice and forensic mental health systems including those diagnosed with major mental illnesses, males and females, aboriginal and non-aboriginal offenders, offenders in prison and released on parole in the community, high-risk violence-prone offenders, and offenders with psychopathic and antisocial personality features. Various studies have indicated that the psychometric properties of the VRS such as interrater reliability, internal consistency, predictive, and concurrent validity are acceptable to good.

Violence Prediction Validity

The majority of criminal justice and forensic mental health work typically requires making reoffending predictions, in particular, violent reoffending predictions. Violent reoffending has a lower base rate or frequency of occurrence than nonviolent or generally reoffending and, therefore, is more difficult to predict. The predictive validity of the VRS can be evaluated by first assessing a target group using the VRS, tracking them for a period of time in the community when they have opportunities to reoffend, and determining the number of persons who reoffended. The association of VRS scores and reoffending can be determined statistically, for example, using correlation coefficients or area under the curve as estimates of the magnitude (i.e., effect size) of the association. A substantial and statistically significant association between VRS scores and violent reoffending could be considered as evidence of the predictive validity of the VRS.

The predictive validity of the VRS has been demonstrated in all the offender and service user groups mentioned previously. Most risk prediction tools can predict violent reoffending at a medium level, that is, one with a medium effect size which can be measured by a statistic such as a correlation coefficient or the area under the curve. For example, an area under the curve of about .56, .64, and .71 are often referred to as *low*, *medium*, and *high effect size*, respectively. The predictive efficacy of the VRS varies from medium to high depending on the sample in question. VRS can predict both violent and nonviolent

reoffending at various time periods post-assessment (i.e., from 1 year to over 4 years) after release to the community. Dynamic predictors were found to predict just as well as static predictors. The predictive efficacy of the VRS is expected to be lower when the tool is applied to a more homogenous group of offenders such as a group of high-risk and high-psychopathy offenders. For such a group, the VRS predictive efficacy is medium but still statistically significant. Samples that are more homogenous (i.e., with a smaller spread or a restriction of range of the group's defining characteristics) are more difficult to discriminate than a less homogeneous group. For these reasons, the predictive efficacy of the VRS is smaller (medium effect size) for a group of high-risk and high-psychopathy offenders (more homogenous) compared to that of an average group of offenders who are less homogenous (medium to high effect sizes).

Assessing Treatment Change and Reoffending

The VRS was also designed to assess risk changes such as changes over time or after risk reduction treatment. To assess change, risk has to be assessed at two or more time points, such as pre- and post-treatment or Times 1, 2, and 3. To determine that the purported risk changes are, in fact, risk related and not a measure of some spurious change, the assessed change must be significantly linked to predicted changes in recidivism. If VRS change scores could be shown to be significantly associated with reduction in reoffending, then such findings could be taken as evidence that the VRS could reliably and validly assess risk change. Risk change research is still at an early stage of development and much more research in this area is required. Very few risk assessment tools have provided empirical evidence that risk changes assessed at 2 or more time points are linked to predictable changes in reoffending.

In a 2012 study with a sample of high-risk and psychopathic offenders who had participated in a risk reduction treatment program, risk reduction assessed with the VRS pre- and posttreatment was significantly associated with reduction of violent reoffending in the community. Such

associations remain statistically significant after controlling for various potential confounds such as pretreatment risk level, psychopathy, ethnicity, length of follow-up time, and time from end of treatment to community release. The increasing body of research evidence indicates that the VRS is a psychometrically sound risk assessment tool that can be used to assess and predict violent and nonviolent reoffending as well as to assess risk changes.

VIOLENCE RISK SCALE–SEXUAL OFFENDER VERSION (VRS-SO)

The VRS-SO is a sexual offense risk assessment and treatment planning tool. The VRS-SO is made up of seven static (i.e., historical, generally unchanging) and 17 dynamic (i.e., potentially

changeable) items linked to increased risk of sexual violence. It is designed to (a) assess risk of sexual violence, (b) identify targets for sex offender treatment intervention, (c) assess readiness for change, and (d) evaluate changes in risk from treatment or other change agents.

Assessing Sexual Violence Risk

In terms of risk assessment, each item is rated on a 4-point scale (0, 1, 2, and 3) with higher item ratings indicating increased risk of sexual violence. The items can then be summed to generate static (range 0–21), dynamic (range 0–51), and total (static + dynamic, range 0–72) scores. These scores indicate the individual's level of risk of future sexual violence, with higher scores on the tool indicating higher levels of risk and the need for more intensive risk management efforts in order to prevent sexual violence. The VRS-SO yields both pretreatment and posttreatment scores; typically, only the dynamic items and resulting total score will change from treatment or other change agents. The pretreatment dynamic and total scores represent the individual's baseline risk at the beginning of treatment, while the posttreatment dynamic and total scores are adjusted to reflect any possible changes in treatment and thus represent the individual's level of risk at posttreatment.

Identifying Treatment Targets

The dynamic items of the VRS-SO are areas to focus treatment efforts. Items rated 2 or 3 are considered to be criminogenic, that is, they have strong links to sexual violence for that individual and should be prioritized in supervision. To assist with linking treatment targets to treatment planning, the VRS-SO dynamic items are organized into three factors termed sexual deviance (e.g., sexually deviant interests, sexual compulsivity), criminality (e.g., substance abuse, aggression, lack of community supports), and treatment responsiveness (e.g., attitudes and thinking facilitative of sexual violence). An individual's pattern of 2 and 3 ratings on these three factors creates a criminogenic profile of the individual's treatment needs. For instance, a man incarcerated for sexually assaulting an adult woman might have few

indicators of sexual deviance (e.g., preference for or arousal to rape, presence of other sexually deviant interests) but may have pronounced concerns in the criminality domain (e.g., history of fights and aggression, poor anger control, alcohol problems, lack of positive community supports) and on the treatment responsivity factor (e.g., negative attitudes toward women and his offense). Treatment for this individual would focus on addressing his negative attitudes and nonsexual criminogenic needs since these are most relevant to his risk of sexual violence, while it would be unnecessary to devote resources into altering his sexual interests and preferences.

Assessing Readiness to Change

The VRS-SO is also designed to assess readiness for, or motivation to, change. The VRS-SO does this through applying the stages of change (SOC) model to each dynamic item. The SOC model grew out of health psychology, and it contends that people go through a series of cognitive, behavioral, and experiential changes and they attempt to work on their problem areas. The SOC model employed is divided into five stages: precontemplation (no awareness of problem area or unwilling to change), contemplation (awareness of problem area but steps taken to address), preparation (recent behavioral changes to address problem area), action (sustained positive behavioral change over an extended period of time), and maintenance (sustained behavioral change that has withstood relevant challenges from high-risk situations). Thus, change occurs on a movable continuum, and people move up and down this continuum as they attempt to remediate a given problem area. These five stages are mapped out for each dynamic item. Individuals receiving a 2 or 3 rating at pretreatment are also assigned a baseline stage of change to indicate their level of awareness of the problem area and their willingness to address it. Very early SOC, such as precontemplation, call for different treatment engagement strategies than more advanced areas (e.g., contemplation, preparation). For instance, an individual rated in Precontemplation on several areas may require motivational enhancement strategies (e.g., empathy and validation, gentle encouragement, rolling with resistance) to prepare the individual

to look honestly at his or her issues and to address them in treatment.

Evaluating Risk Change

Risk change is evaluated on the VRS-SO using the SOC model through rating 2- or 3-rated items on their respective stage of change at the beginning and end of treatment. Individuals advancing one stage of progress (e.g., contemplation to preparation) on a given item receive a 0.5 deduction from their pretreatment score on that item, two stages a 1-point deduction (i.e., 2×0.5) up to a maximum of 1.5 points. The one exception is movement from precontemplation to contemplation, which is given no deduction since there is no risk-relevant behavioral change (i.e., the change is simply one of going from no awareness of a problem area to developing such an awareness, with no steps taken to manage it). The change ratings are then summed across each of the criminogenic items to generate a change score. The change score, in turn, is deducted from the pretreatment score to yield a posttreatment score. In turn, the change score and baseline pretreatment score are used to estimate rates of sexual and violent recidivism for a given case using an online electronic workbook. The VRS-SO can also be used with the Static-99R.

Relevant Research and Conclusions

Research from Canada, New Zealand, Germany, and Australia supports the validity and reliability of the VRS-SO. This body of research demonstrates that the VRS-SO is a strong predictor of sexual violence, with high scores predicting higher rates of sexual recidivism and low scores predicting lower rates of this outcome. The research has also shown that the static and dynamic scores on the VRS-SO play different roles in the prediction of sexual violence, and the two work better together than on their own, what is sometimes referred to as *incremental validity*. Finally, research on treated samples of sex offenders has shown that the men attending treatment tend to make significant gains from pre- to posttreatment. The resulting change scores have been found to be significantly associated with decreased sexual offending. That is, higher levels of positive change corresponding to decreases in risk have been

associated with reduced offending behavior in the community following release. These research results support the VRS-SO as a promising tool for use with adult male sex offenders to assess risk and evaluate changes in risk to inform risk management.

Violence Risk Scale–Youth Version (VRS-YV)

It is important to assess risk of future violence for adolescents who have been charged with or convicted of criminal offenses, especially when these offenses are of a serious and/or violent nature. However, assessment of violence risk in and of itself is insufficient. Risk reduction and the prevention of future violence should always be viewed as the ultimate goal of violence risk assessment. As such, tools that can bridge the link between violence risk assessment and violence reduction treatment can be beneficial to service delivery providers. The VRS-YV is arguably one such assessment tool. This entry provides an overview of the VRS-YV as well as research on its effectiveness.

Overview of the VRS-YV

The VRS-YV is part of a family of risk assessment and treatment planning tools developed by

Stephen Wong and colleagues. These include the Violence Risk Scale (VRS) and Violence Risk Scale–Sex Offender Version (VRS-SO). Both the VRS and VRS-SO have been adapted for use with youth, with the VRS-YV being the youth version of the adult VRS.

The VRS-YV is a 23-item clinician-rated measure designed to assess adolescents' risk of violent offending and inform interventions intended to reduce violence risk. Consistent with the adult version of the tool, the VRS-YV includes both historical or stable risk factors and dynamic or potentially changeable risk factors associated with future violence as shown in Table 1.

The four stable and 19 dynamic factors are rated on a 4-point scale (from 0 to 3) using broad descriptions of the constructs measured by each item included in the manual. Higher ratings indicate stronger associations between the item and future violent and/or aggressive behavior. Ratings for each item are then added together to provide static and dynamic totals and an overall score.

The VRS-YV dynamic items can also be used to identify targets for intervention and measure therapeutic change. Dynamic items rated highly (i.e., items scored as a 2 or 3) are conceptualized as problem areas requiring treatment and therefore are considered treatment targets. Each treatment target is rated pre- and posttreatment using a modified version of James Prochaska's 1992 stages of change model. The original model was used to capture efforts to change health-related behaviors. For instance, when attempting to quit smoking, people usually move along a behavioral continuum whereby they first deny they have a problem (pre-contemplation) to accepting that they might (contemplation), to preparing to making positive changes (preparation), to consistently making such changes over a substantive period of time (action), and then to maintaining such gains in the face of high-risk situations (maintenance). Using this modified stages of change model, numerical values are assigned to these stages of change and the amount of change observed on each treatment target can be assessed at Time 1, reassessed at Time 2, and quantified. Such a mechanism provides a structured way to adjust risk to account for changes made over time, with development, and during the course of treatment.

Table 1 VRS-YV Stable and Dynamic Factors

<i>VRS-YV Stable Factors</i>	<i>VRS-YV Dynamic Factors</i>	
Early onset serious antisocial behavior	Violent lifestyle	Mental disorder
Criminality	Callous/unemotional	Substance abuse
Instability of family upbringing	Criminal attitudes	Impulsivity
Exposure to antisocial behavior in family	Negative attitude toward education	Cognitive distortions
	Antisocial peers	Family stress
	Interpersonal aggression	Interaction with caregivers
	Poor emotional control	Social isolation
	Violence during institutionalization	Community disorganization
	Lack of insight	Poor compliance
	Weapon use	

Research on the VRS-YV

Preliminary research on a diverse sample of 147 Canadian young offenders referred for assessment and treatment services at a local community mental health facility suggests the VRS-YV performs similarly to other established youth forensic risk tools. For instance, the VRS-YV could be rated consistently and reliably, and VRS-YV static, dynamic, and total scores significantly predicted general and violent recidivism with moderate to high accuracy. Additional analyses further suggested that VRS-YV items tended to *hang together* in three main groups, or factors: *interpersonal aggression, antisocial tendencies, and family problems*. These factors may reflect constructs underpinning violence risk and could be used to assist case formulation and treatment planning efforts. Treatment planning may also be informed by examining the pattern of VRS-YV scores which form a dynamic risk profile (i.e., an individual fingerprint of sorts, which visually illustrates the hills and valleys of relative treatment targets and areas of strength for an individual youth).

Research examining the capacity of the VRS-YV to assess change merits further exploration, especially in light of positive findings obtained in research evaluating adult counterparts (i.e., VRS, VRS-SO).

Final Thoughts

Preliminary research supports the use of the VRS-YV with youth who may be referred for specialized assessment and treatment services (e.g., serious and violent young offenders). While additional research employing larger samples of more treated youth is clearly required, the VRS-YV is a promising tool that would seem to merit further investigation.

Violent Offenders

Violent offenders are usually defined by the crimes they commit—that is, violent offenders are offenders who have committed violent crimes—rather than by some inherent characteristic of the person, such as a genetic defect; no such defect or other similar definitive feature has ever been found. Thus, it is appropriate to describe individuals by their behaviors such as *an individual with a history of violent offending* or some similar descriptor rather than by using labels such as *violent offenders* that suggest the presence of some inherent personal features.

There is no universally accepted definition of violent crime; many researchers and authors use their own definitions. Generally speaking, however, crimes that cause physical or significant psychological harm to the victim are considered to be violent crime in contrast with property or nonviolent crimes. One could, however, argue that all crime can cause harm or serious harm to others, even the so-called property crimes. To make things even less clear, new categories of crimes continue to be introduced due to technological or other developments. For example, online bullying is a recent addition; there is no physical or even visual contact between the perpetrator and victim, but it is considered a violent offense. A further caveat is that different countries or jurisdictions use different terms or variations of terms to describe the same or similar acts. Thus, the debate of what constitutes violent crime cannot be easily settled.

While there may not be consensus on what constitutes violent crimes, there is universal consensus that criminal violence must be reduced so all can live in a safer society. There are many approaches to reduce criminal violence such as that based on a public health approach to reduce domestic and spousal violence or the use of early interventions to reduce school bullying and youth violence. This entry focuses on one approach, the Violence Reduction Program (VRP), which provides violence reduction forensic treatment to individuals who are at substantial risk to reoffend violently, the so-called violent offenders, although it begins with a discussion on the types of offenses that are generally considered violent and nonviolent crimes

Violent and Nonviolent Offenses

The types of offenses listed in this section are for general reference only and *should not be taken as exhaustive or definitive*. What is important is to define the terms *violence* and *violent crime* when these terms are used to avoid misunderstanding or miscommunication.

Violent crimes generally consist of homicide-related offenses (murder, attempted murder, and manslaughter), kidnapping, arson, forcible confinement, wounding, robbery, terrorism, various assault offenses, and any sexual assault other than noncontact sexual crimes such as exhibitionism and voyeurism.

Nonviolent crimes are all crimes other than violent crimes such as theft and other property-related offenses, breaking and entering and related offenses, fraud and related offense, and noncompliance and related offenses, such as failing to appear and jumping bail.

There are some crimes that are difficult to categorize partly because their classifications as violent or nonviolent depend very much on the seriousness of the offense, for example, many drug offenses, crimes against the state, and driving offenses.

VRP

The VRP was developed by Stephen Wong and Audrey Gordon; it is an evidence-based program that uses cognitive behavioral interventions to treat problem areas that cause or are closely associated with the person's criminality and violence. The primary objective of the VRP is to reduce recidivism, especially violent recidivism.

Theoretical Foundations

The development of the VRP was guided largely by the work of Don Andrews and James Bonta and their Risk-Need-Responsivity principles formulated to inform correctional assessment and rehabilitation. Briefly, the Risk principle posits that treatment intensity should match individuals' risk level, higher risk offenders should receive higher intensity treatment than lower risk offenders. The Need principle specifies that problems that influence or are strongly associated with an individual's criminality and violence (i.e.,

criminogenic needs) should be targeted in treatment to reduce the likelihood of recidivism. Within the Responsivity principle, *general responsivity* maintains that cognitive behavioral approaches should be used to promote positive change within a functional working alliance with staff. *Specific responsivity* suggests that interventions should be adapted to the individual's motivation, learning style, cognitive capability, and cultural heritage. Treatment programs that adhered to Risk-Need-Responsivity principles in design and delivery have been assessed as being more effective in reducing recidivism than programs that do not.

Risk Assessment and Treatment

In the VRP, risk assessment and treatment are closely integrated. Risk is assessed using the Violence Risk Scale (VRS), a validated violence risk assessment tool also developed by the VRP authors. VRS scores indicate the level of violent risk and can be used to guide the intensity of treatment (Risk principle). The VRS also identifies treatment targets (Need principle), the person's readiness or motivation for treatment (Responsivity principle), and risk change over time or between pre- and posttreatment.

Program Content and Delivery

The VRP uses cognitive behavioral therapeutic (CBT) approaches to increase participants' awareness and understanding of how their thoughts, feelings, and behaviors (TFB) are linked to their offending behaviors. Participants are taught relevant skills necessary to modify their problematic and offense-linked TFB patterns. For example, someone who lacks appropriate interpersonal skills, such as conflict resolution, or lacks emotional management skills, can learn appropriate skills and practice them in daily living to reduce the risk of reoffending. Other maladaptive behaviors and cognitions linked to offending behaviors can be identified and adaptive ones acquired. TFB linked to offending, or treatment targets, can be identified with the VRS.

The VRP is delivered based on a three-phase treatment model; learning in one phase is built on learning achieved in earlier phases. Phase 1 or

Looking in the Mirror includes VRP modules developed to enhance participants' understanding of the development and maintenance of offending and violent behaviors, in part, through reflecting on their past and present problems as well as the development of therapeutic alliance and program engagement with staff. The VRS is also used in Phase 1 to identify treatment targets (violence-linked TFBs). The VRP modules within Phase 2 or *Breaking the Cycle* focus on learning relevant risk-reduction skills using CBT approaches to mitigate treatment targets and TFB patterns identified in Phase 1. By the end of Phase 2, program participants would have developed an *offense cycle*, which details the personal (dysfunctional TFB) and situational factors linked to their violent offending. Offenders tend to ignore or minimize aspects of their TFB that may be hurtful, incriminating, or likely to evoke guilt or escalate to violence. Thus, participants are encouraged to put together their offense cycles in three separate but related time segments in order to delineate clearly their TFBs prior to, during, and after the offense. Only when they adequately grasp the importance of all relevant TFBs, they can develop comprehensive and effective interventions. Phase 3 or *Relapse Prevention* represents the consolidation and strengthening of Phase 1 and Phase 2 learning, moving toward the termination of the VRP. In Phase 3, the focus is on the generalization of newly learned behaviors and cognitions acquired in Phase 2 to everyday situations in a custodial setting or, if possible, in the community with appropriate support, encouragement, and monitoring from staff. The application of learning to their everyday environment typically starts in Phase 2 when participants begin to practice taught skills. As a part of Phase 3, participants are required to develop a personal relapse prevention plan linked to their offense cycle. For TFBs identified in each time segment in their offense cycle, participants are required to identify risk-reducing interventions to counter them.

Treatment is a lifelong process of successfully managing one's behaviors while negotiating and overcoming challenges. Continuity of care is essential to support newly learned skills. Thus, the VRP should be followed by a care plan based on offenders' individual relapse prevention plan so that participants can be effectively transitioned to

their next step in life, whatever that might be, and not left to fend for themselves entirely on their own.

Figure 1 illustrates the VRP three-phase model, the corresponding stages of change, and descriptions of tasks within each phase.

Delivery Format

The VRP is primarily designed as a group-based program. It can also be delivered individually by tailoring the program to those not amenable to group-based programs, such as offenders with learning disabilities or with acute mental health issues.

Program Length

The VRP participants progress in the program by achieving set program objectives rather than by completing a specified number of treatment sessions. Invariably, participants progress at different rates based on personal and situational factors such as their level of risk, need, intellectual abilities, size of treatment group, staffing levels, and other competing priorities. There is an option to incorporate existing treatment modules such as a mandated substance abuse module, in the VRP,

which may also affect program length. As a general guidance, for a group of individuals with a significant number of treatment targets (typically medium- to high-risk offenders), the VRP can be delivered in 10–12 months.

VRP Manuals

In addition to the VRS with its own manual for administration, VRP delivery is guided by three program manuals that provide detailed instructions for session, module and phase delivery, and treatment progress evaluations. They are the *VRP Facilitator's Manual*, *Supplementary Facilitator's Manual*, and the *Program Participant's Manual*.

A 24/7 Treatment Model

Within the VRP, a central goal is that participants, with staff support, apply what they learn in group or individual therapy to their daily living—for example, to practice learned skills in interactions with staff and peers, at work, in leisure and recreational activities, in educational or vocational upgradings, 24 hours a day, 7 days a week. In essence, time outside designated treatment hours can be constructively used to extend and consolidate treatment gains. There are many

Figure 1 Violence Reduction Program three-phase treatment delivery model

advantages to this approach. Acquired skills are best consolidated by practicing and generalizing them to multiple new situations. Feedback and reinforcements can further shape these behaviors; appropriate prosocial behaviors can be strengthened, and inappropriate behaviors, such as those linked to the individual's past violence, can be pointed out and addressed swiftly. New skills are best learned if one is immersed in an environment that supports the use of such skills vis-à-vis learning a new language. Line staff who look after the offenders' day-to-day needs typically spend more time and have more opportunities to observe participants' behaviors compared to VRP program staff whose observations may be more limited to within formal treatment sessions. Thus, both program and nonprogram staff who have meaningful contact with VRP participants have important roles to play to support VRP program objectives—an extension of the multidisciplinary team concept to include all staff with client contact. Such an approach can also help to engender a supportive change-oriented ethos, thereby fostering an overall positive working environment for all concerned. While the 24/7 treatment approach is not a new concept, few treatment programs have applied it in a custodial setting.

Assessing Treatment Change in Custodial Settings

While changes observed in formal treatment sessions or assessed with self-report questionnaires are important, behavioral observations in participants' everyday living environment can help to determine the veracity of their behavioral changes. For example, offense-related behaviors easily observable in the community, such as overt aggression, may be *repackaged* as verbal intimidation or covert bullying behaviors because of close monitoring and severe consequences in prison environments. The prevalence of these repackaged *offense analogue behaviors* (OABs) is often an indication that the root problems underpinning past antisocial acts have not changed. For each treatment target identified by the VRS, there should be a corresponding and idiosyncratic set of OABs. Change should be evidenced by reduction in OABs across situations with a corresponding increase in appropriate prosocial behaviors or

offense reduction behaviors (ORBs) that can be used to successfully manage past problem areas. For example, verbal intimidations and bullying (OABs) should be reduced and replaced by assertive conflict resolution or problem-solving approaches, which are the corresponding ORBs, to deal with real-life challenges.

Assessing the prevalence of OABs and ORBs is critical in determining the presence and consistency of positive (risk reduction) changes in a controlled environment. The VRP's 24/7 model of treatment provides staff with many opportunities to observe and collect behavioral evidence in support of assessments of change or lack thereof based on the offender's OABs and ORBs—an evidence-based approach to evaluate treatment progress.

Progress and Treatment Outcome Evaluation

Progress through the VRP is assessed with rating tools provided in the VRP manual for sessions, modules, and for each of the three phases. Progress is based on the participant's understanding of program material and applying the learning to relevant situations including reducing OABs and increasing ORBs. At the end of treatment or, if necessary, at certain points during treatment, the VRS can be used to assess overall risk changes based on the participant's progress through the stages of change rubric detailed within the VRS. The overall objective of the VRP is to reduce reoffending in the institution and the community. Treatment progress should lead to overall recidivism reduction, but the latter can only be observed by actual reduction of recidivism in the community and, to some extent, by the reduction of misconduct in the institution.

Treatment outcome results have been examined in a number of studies using different offender groups and research designs. The studies were based either on the VRP or an earlier, but similar, version of the program, the Aggressive Behavioral Control (ABC) program developed in Canada in the mid-1990s. Outcome evaluations of the ABC program allow for much longer follow-up time than VRP-specific studies.

Risk-reduction treatment is sometimes used to reintegrate offenders housed in a very high-security (e.g., super-maximum security) settings to

regular high-security settings. Individuals are usually placed in these settings after committing extreme violent acts while incarcerated and their preparation for release to the community often is not the primary objective for intervention. Reported in 2005, 30 offenders from a super-maximum prison in Canada were transferred to the ABC program for treatment in preparation for potential downgrade in security and transfer to a regular high-security prison. The majority (90.3%) were diagnosed with antisocial personality disorder and 80.6% with substance-related disorder. They spent a mean of 6.9 months in treatment. Twenty-five (25) or 83.3% of them were successfully reintegrated into a lower security facility posttreatment without returning to the prison they came from within a 21.3-month follow-up period. Posttreatment institutional offense rates were also lower than pretreatment rates.

In some settings, treatment can be useful to assist extremely disruptive offenders with severe history of violence to better regulate their own behaviors such that they can be managed in the same setting with less restrictive procedures, for example, without the routine use of personal restraints in their movements or the need for constant intensive supervision. Between 2004 and 2006, four prisoners who fit this description, who had committed murder while incarcerated, held in isolation in the highest security prison in England and characterized as extremely difficult to manage, participated as a group in the VRP. In 2006, an independent evaluation of the treatment outcome indicated that participation in the VRP has produced a marked improvement in prisoners' conduct. Violence-related behaviors had decreased, and interpersonal skills had improved. The authors indicated that, in part, change was due to much improved communications and interpersonal interactions between prisoners and staff thus enabling staff to proactively diffuse high-risk situations prisoners found themselves in. As well, prisoners were better able to manage their emotionally charged reactions. Some limited follow-up information indicated that skills developed during the VRP have since been maintained in less supportive new locations for these prisoners. The qualitative results are consistent with other findings showing violence reduction and behavioral improvement after participation in the VRP,

although no firm conclusions could be drawn based on such a small sample size.

Members of various organized gangs, such as motorcycle gangs, and less organized street gangs are particularly challenging for prison authorities to manage and rehabilitate because of their gang affiliation, proneness to peer group pressures, and habitual reliance on violent behaviors. Risk-reduction treatment is an option to reduce their risk of violence but few programs have undertaken systematic evaluation of program efficacy for violence reduction among gang members. Reported in 2006, a group of 40 male treated gang members was compared to 40 untreated or less treated male match controls with a similar demographic profile, including age and race, type of gang affiliation, criminal history, and reoffending risk to ensure that the groups were comparable. Over 78% of the treated group completed the ABC program, the rest attended other CBT risk-focused programs; all were treated for about 7.5 months. In a 2-year follow-up after release to the community, the treated group had significantly fewer and less serious violent and nonviolent recidivism than the controls. After treatment but before release to the community, the treated group also was involved in fewer incidents of major institutional misconduct than the control group. The results suggest that risk-reduction treatment, such as that in the ABC program, is effective in violence reduction even for gang-affiliated male offenders.

Offenders with significant psychopathic personality features are often considered difficult to engage in treatment and are even deemed untreatable by some. As such, risk-reduction treatment of violence-prone offenders with many psychopathic personality features presents major challenges to most treatment programs. In two studies reported in 2012 and 2013, a sample of 150 medium- to high-risk offenders with significant psychopathic features (assessed with the Psychopathy Checklist-Revised) were treated in the ABC program for about 8 months. They were assessed with the VRS to determine their pre- and posttreatment risk levels and to assess changes in risk. The assessments were based on careful reviews of case file information, a well-established and accepted way of data collection for this type of research design. There was a significant reduction in post- compared to pretreatment risk level. In a 5-year

follow-up, the risk reduction was found to be linked to the reduction in violent recidivism in the community even after accounting for potential confounds such as level of risk, length of incarceration between treatment termination and community release, and most importantly, the level of psychopathy. The results suggest that risk changes are possible even among high-risk psychopathic offenders. The reduction in risk and recidivism in this offender sample was very likely but not definitively attributable to the effects of treatment, as there was no control group included in this research design.

Another study examined the efficacy of treating high-risk and psychopathic offenders with serious violent criminal histories in the ABC program using a case-matched control group design. Reported in 2012, 32 treated male offenders were matched with 32 male offenders who were either untreated or received some standard routine treatment (treatment-as-usual) within the prison regime. They were matched on violent and nonviolent criminal histories, age, Psychopathy Checklist-Revised scores, and VRS scores and followed up for 7.4 years in the community to determine their recidivism. There were consistent trends of lower violent and nonviolent recidivism in the treated group, but the differences were not statistically significant, probably related to low statistical power due to the small sample sizes. When the seriousness of recidivism was assessed using sentence length as a proxy measure, the treated group showed large, consistent, and statistically significant reduction of offense severity compared to the controls. The results suggest that treatment of a group of high-risk and psychopathic offenders can lead to the reduction of the seriousness of reoffending—a harm reduction effect. The program duration of 8 months for these offenders was likely insufficient to produce an optimal outcome. Despite the less than optimal *treatment dosage* and having only 32 treated offenders in the group, participation in risk reduction-focused programs, such as the ABC, can reduce reoffending severity. Human costs aside, the offense severity or sentence length reduction alone translated into the equivalent of a net savings of Can\$6.2 (approximately US\$4.9) million reduction in incarceration costs, as the treated group served significantly shorter sentences than the controls even after factoring in the programming cost. Replications of

the study with larger offender samples in different criminal justice settings are essential to provide further support of the present findings.

Final Thoughts

Despite the lack of precision in the definition of violence, the need for reducing violent reoffending, however defined, is universally acknowledged. The VRP, based on Risk-Need-Responsivity principles and CBT approaches, is an empirically tested treatment program designed to reduce violent recidivism and institutional misconduct in forensic clients. Careful program evaluation studies have demonstrated the efficacy of the VRP in the treatment of offenders with psychopathy, housed in super-maximum institutions, and offenders with gang affiliations. That the VRP is effective in reducing reoffending, even in these very challenging offender populations, provides support that the VRP is robust in its design and model of treatment delivery. However, no randomized controlled trial, the gold standard to assess treatment efficacy, has been undertaken on the VRP. The generalization of the evaluation results is limited by the small sample sizes of these outcome studies and by the possible contributions of various moderator variables. More evaluation studies are called for in future research with the VRP.

--- **VIOLENT OFFENDERS, CATEGORIES OF** ---

Aggression is generally defined as behavior directed toward another individual, which is carried out with the immediate intent to cause him or her harm. Violence is considered to be a more severe form of aggression in which harm is intentionally inflicted, ranging from a physical assault in a domestic setting to an aggravated assault, robbery with a firearm, sexual assault, or the most severe in outcome: homicide. Absent from the literature is a description of the point at which an aggressive act is considered a violent act. There are behaviors that are clearly violent (e.g., murder, physical assault), but there are other cases (e.g., uttering threats to cause harm, attempted robbery) whereby the distinction is less clear and classification is more challenging. Interpersonal aggression and violence have been studied from various theoretical perspectives and are understood to be influenced by numerous environmental, social, neurobiological, and cultural features. The classification and validation of violent offender categories not only can assist the theoretical understanding and knowledge of violence but also can inform the development and advancement of correctional treatment programs aimed at decreasing violence and aggression. This entry provides an overview of the two principal types of

violent behavior and their characteristics and then examines arguments against violent offender categories.

Heterogeneity of Violence

Numerous attempts have been made to distinguish subtypes of violent behavior in offender and nonoffender samples. However, the basis of differentiating subtypes has varied considerably among studies, with the most common distinctions based on differences in the form or function of the aggression.

In terms of the form of aggression, classifying aggressive subtypes has been based on whether the behavior is physical versus nonphysical, active (hitting another person) versus passive, direct versus indirect, overt versus covert, and relational versus social. Violent offender categories based on the function of aggression examine the reasons for the violent act or the motivation underlying the behavior. For example, violent behavior is defined differently in a situation where one is defending oneself from a perceived attack versus using violence to obtain money or enact revenge.

Although varied in nomenclature, two overarching, multifaceted typologies emerge in terms of classifying violence based on function. The first category is *affective-impulsive-hostile-reactive violence* and is described as an emotionally driven, impulsive form of aggression in response to a perceived provocation. It is most commonly referred to as *reactive aggression* and is characterized by affective instability, disinhibition, and high levels of arousal. The second category, *premeditated-instrumental-predatory-proactive violence*, is an unprovoked aggressive act designed to meet a predefined goal or objective (i.e., the goal, such as finances, power, drugs, or sex, is indirectly related to the violent action). Most commonly referred to as *instrumental aggression*, it is characterized as a violent act initiated by the individual as a means to achieve a specific goal.

Importantly, there are a number of key elements that differentiate between these two categories of violent offenders. What follows is a description of the elements of each, in an attempt to aid in conceptualizing categories of violent offenders.

Premeditation or Planning

A key factor differentiating the two subtypes of violence is the degree of planning/premeditation of the aggressive act. Instrumental aggression typically involves some degree of planning or premeditation related to the incident (e.g., purchasing a weapon and clothing for a robbery). This is in contrast to a reactive aggressive incident, which typically occurs impulsively with little to no degree of planning or forethought.

Perceived Provocation

Another distinguishing factor is the presence or absence of a perceived provocation and the presence or absence of negative affect (e.g., hostility, anger). Specifically, for reactive violent offenders, the perception of a threat (physical or verbal) to them is the precipitating factor for aggression. This is in contrast to *instrumental violent offenders*, whereby the primary objective is goal-driven and not based on the perception of provocation.

Goal Directedness

The presence or absence of a goal external to the aggressive act is another key element. This difference is described in terms of the primary versus secondary goal of the incident. In a hostile aggressive incident whereby someone is provoked (e.g., bumping into someone in a crowded bar), the primary goal is to defend oneself against the antagonist. Conversely, in an instrumentally aggressive incident, the primary goal is not to defend but rather to meet an objective (e.g., obtain money or desired objects), and aggression or violence is the *means to obtain this objective* (e.g., violent robbery).

Anger or Arousal Level

Finally, an individual's level of emotional arousal is another common distinction in violent subtypes. The presence of anger or hostility, often as a result of interpersonal conflict, is a differentiating characteristic of reactive versus instrumental aggression. Reactive aggression is also referred to as *hot-blooded* aggression. This

is in contrast to instrumental aggression, which is *motivated by goals, not emotions* and is consequently referred to as *cold-blooded* aggression.

Arguments Against Violent Offender Categories

Despite the fact that the previously mentioned characteristics (e.g., degree of planning, underlying motivation) are commonly reported upon in criminal proceedings and psychological assessments, discrepancies exist in the classification of violent subtypes. Specifically, the greatest debate is whether subtypes should be placed into precise dichotomous categories or fall on a continuum. Brad Bushman and Craig Anderson argue against the classification of violent offender categories, contending that the two subtypes of violence are an unrealistic depiction of violence, as real-world events are seldom purely instrumental or purely reactive. They point to the fact that numerous factors are involved in each violent incident, and given the multitude of events, factors, and characteristics that influence the outcomes of a given violent act, a bimodal classification system is unreliable because the boundaries for each subtype are not distinct.

Michael Woodworth and Stephen Porter have been more restrained in their perspective but have also argued that violent behavior is not purely bimodal. They have conceptualized that it falls on a continuum ranging from purely reactive to purely instrumental, with a mixed-motive dimension falling in the middle of the continuum.

Future Research

Although differentiating criteria have consistently characterized reactive aggression as an impulsive, emotionally charged response to a perceived threat type, whereas instrumental violence is depicted as a controlled, unemotional, goal-oriented, and often planned act of physical violence, few studies to date have attempted to validate these violent offender subtypes. Moreover, even fewer studies have attempted to substantiate the arguments for a bimodal classification of violent offenders or classification of

violence on a continuum. Consequently, violent offender categories based on motivations underlying the violence merit further consideration.

VIOLENT OFFENDERS: TREATMENT APPROACHES

Successful approaches to the treatment of violent offenders reduce the risk of future violent and nonviolent reconviction by remediating changeable characteristics of offenders and their environments that are empirically linked to criminal risk. Remediation often requires (a) supporting offenders to reconceptualize how they understand or view themselves, their lives, and other people and (b) teaching them skills that develop their capacity

to live more positive, constructive, and prosocial lives, as an alternative to crime. Increasingly, treatment approaches also recognize the importance of concrete preparations for reentry into the community and the development of a supportive environment for the offender, during and after treatment. Together these components have been demonstrated to reduce the likelihood of conviction and enhance desistance for violent offenders.

Violence is a diverse class of offenses including minor to severe physical assaults, violent sexual assaults, armed robberies, and homicides, thus varying widely in severity and victim injury. Some people will only commit a single violent offense in their lifetime, and a small minority of violent offenders specializes in some way (e.g., committing offenses only against their adult intimate partner). But when treatment is intended to reduce the risk posed by offenders to the community, the focus is not on people who commit offenses only occasionally. Instead it is on repeat violent offenders. Treatment approaches take as their starting point the *what works* research literature for rehabilitating offenders and the Risk-Need-Responsivity (RNR) model. Most research on treatment has been conducted with adult male offenders with recent convictions for violent offenses, so they will be the main focus of this entry, which addresses treatment-relevant characteristics of violent offenders and outlines a general treatment approach.

Treatment-Relevant Characteristics

A well-established criminological finding is that a very small proportion of people—often around 5%—commit half or more of the offenses occurring in a community. Those who repeatedly commit violent offenses are also high-frequency, versatile general offenders; most of their offending is nonviolent. Furthermore, they are people whose difficult characteristics may have begun at conception; who are exposed to significant family-based adversity—poverty, unemployment, criminal modeling, abuse, and neglect; and whose problematic behavior can be detected and documented empirically soon after birth. By late childhood or early adolescence, they are typically achieving a number of antisocial milestones such as lying, stealing, fighting, bullying others, truanting from school,

low school achievement, and alcohol and drug misuse. Their first convictions for crime occur early, and unlike most people with criminal convictions, they persist, often well into their fourth decade. As adults, alongside their prolific, diverse, and intermittently violent offending, other signs of personal and social dysfunctions interact reciprocally with their criminal lifestyles. They tend to father more children than others; are less likely to support them and more likely to hit both children and partners; spend more time unemployed or supported by illegal income; spend more time dealing with significant psychiatric disabilities—including antisocial personality disorder, drug and alcohol abuse, schizophreniform disorder, anxiety and depression, post-traumatic stress disorder, and suicide attempts; and have low levels of educational attainment and poor financial management skills. Finally, they have poorer indices of physical health even in their early 30s and often fail to attain stability of accommodation, relationships, and employment until late middle age. Because of the extent of their difficulties, the negative impact of their behavior on others, and the demands they place on social service systems extending well beyond their involvement with the criminal justice system, risk-reducing treatment with violent offenders is likely to be much more effective if it is integrated with other forms of assistance and support for them and their families. The co-occurrence of diverse criminality and violence and correspondingly overlapping dynamic risk factors mean treatment is best oriented toward the offender's overall criminal propensity, not toward violent offending specifically.

When assessed for treatment, many high-risk, persistent, and violent offenders score highly on psychopathy—based on one of the Psychopathy Checklist scales, which don't eliminate people with high levels of negative emotionality if they otherwise meet the criteria—alongside other difficult personality disorders. They may give the impression of being suspicious, irritable, and unfriendly and unmotivated to engage in personal change. They are easily stressed, leading to emotional lability and anger, readily develop feelings of victimization, are hostile and suspicious of others' motives, antagonistic, disagreeable and mean, aggressive, untrustworthy, egocentric, and noncompliant.

The most successful treatment programs are cognitive behavioral; they require offenders to reflect on their internal psychological world and to master new skills that will enable them to live more satisfying prosocial lives. But high-risk, persistently criminal, and violent offenders lack self-reflection and self-control. They give up readily when they find tasks hard, and changing behavior is difficult for most people. Deficient verbal abilities and a range of other neuropsychological impairments, a history of failing at school, negative attitudes to new learning, and a low personal agency all contribute obstacles to effective treatment.

General Treatment Approach

All of these treatment population characteristics need to be taken into account in developing a treatment approach. The treatment of violent offenders has mainly occurred in correctional settings, with the exception of the perpetrators of family violence, where community-based organizations have had a more prominent role in intervention development and delivery. Historically programs were relatively brief and probably not effective. They often targeted one or two relevant changeable psychological characteristics (e.g., patriarchal attitudes, poor anger control). Since the promulgation of the RNR model and the development of more sophisticated methods of assessing treatment needs, using assessor-rated tools based on dynamic risk factors, it has become clearer what is needed to provide effective treatment.

Utilizing the RNR Model

All 15 principles comprising the RNR model are relevant, with the RNR principles being the most important. The *Risk* principle states that intervention resources should be reserved for higher risk offenders because changing their propensities for crime will have the most impact. But with these offenders' high levels of need and challenge, programs need to be intensive to have an impact. The *Need* principle emphasizes that treatment time should mostly be spent working on changing factors that are predictive of recidivism (i.e., criminogenic needs, also called *dynamic risk factors*), and the *Responsivity* principle states that treatments will work better when based on the most effective methods of change (i.e., typically

cognitive, behavioral, social learning) and when responsive to those offender-based obstacles to engaging in and benefiting from the program.

The RNR model is best thought of as scaffolding that can support the development of myriad diverse interventions; it is not a template per se. In principle, the design of a specific intervention for violent offenders integrates aspects of etiological and rehabilitation theories with empirical research into how programs change risk. Etiological theories inform *what* a program should address: the criminogenic factors relevant to persistent and violent offenders. Rehabilitation theories inform *how* changes are to be effected: the processes of treatment. For violent offenders, comprehensive rehabilitation theories are still to be proposed, although the growing provision of intensive programs suggests implicitly a slowly evolving theoretical framework.

Value of Group Treatment

Group treatment is the preferred modality, with individual interventions used as needed. Group treatment enables offenders to spend far more time in treatment, and because many risk factors involve interpersonal processes, groups provide a context in which to work practically on relevant issues. Furthermore, offenders may be more influenced by feedback from each other than from therapists; so if a prosocial group climate is created, it is likely to be more influential than the therapists alone.

Readying Offenders for Change

Commonly, treatment is structured into three phases. First, efforts are directed toward readying offenders for change. Typically, violent offenders do not volunteer for treatment and do not present for assessment motivated to change. So the first phase is spent developing working alliances with therapists, socializing offenders to the treatment process, developing trust among group members, completing the therapists' understanding of the relevant assessment information (e.g., current lifestyle, offense triggers and processes, schemas supporting violence), and establishing priorities for change. The phase is complete when the offenders are ready to engage in cognitive and behavioral change related to their dynamic risk factors. Some offenders may need individual therapy prior to joining a group, if their therapy-disrupting behavior is too severe for group participation.

Building Offenders' Capacities

The second phase is the core: working on stable dynamic risk factors by building offenders' personal and interpersonal capacities. The aim is to improve offenders' abilities to construct more satisfying and socially competent lifestyles so that they can move away and, more important, stay away from the criminal justice system (e.g., by developing relationship, communication and problem-solving skills, alternative means for managing stress and distress, strategies for reducing drug use and by finding meaningful ways to occupy time).

Supporting Continuing Growth and Reintegration

However, high-risk and violent criminals, even if they do well in treatment, will finish in a preliminary stage of change. To remain in the next facility or the community long enough to consolidate these changes, they need (a) some *emergency* self-control strategies for managing acute triggers for crime and violence (e.g., provocation to fight) in the release community and (b) a transition environment that minimizes contact with destabilizing influences (e.g., alcohol, drugs, criminal peers, loss of accommodation) and maximizes prosocial resources. So in the third treatment phase, therapists support the offender in developing strategies for managing acute risk factors (i.e., *relapse prevention*) and reintegration planning: working out the next steps for generalizing change into the community or into a less structured environment. Release planning is important; in the absence of systems that provide structured, formal postrelease support, an individual plan that includes accommodation, prosocial emotional and practical support, adequate financial resources, and meaningful time occupation has been shown to predict longer community survival in men who otherwise tend to return to prison quickly.

Even though most treatment is delivered in a group, it should still be matched to each individual within that group, an approach that is most easily achieved with high-quality assessment information about that offender, keeping a close eye on his progress, and by using a rolling group format, where a new member enters the group when another member graduates. Closed cohort

groups—in which about 10 men progress through a fixed sequence of modules together, starting and ending on the same dates—are more common and easier to administer but cannot be as tailored and cannot easily give variable dosages (i.e., time in treatment) depending on need.

State-of-the-art programs provide the group treatment within a dedicated residential environment: usually in a prison. These units are often run by both therapy and security staff; although their roles are distinct, all staff and all residents share values and practices that promote prosocial behavioral change in residents. These program communities provide invaluable opportunities for prosocial socialization and for practicing new skills and therefore are likely to extend and enhance the effects of group therapy as well as provide more opportunities to observe behavioral change (or its absence).

High-Intensity Treatment Programs

In some parts of the world, sentencing requirements mean that very high-risk violent offenders spend very little time outside of custodial environments. But in countries such as the United Kingdom, Canada, Australia, and New Zealand, high-risk offenders may have eligibility for parole. Two decades ago, these offenders may have been regarded as untreatable, but in several parts of the world, increasingly sophisticated and intensive treatment approaches are developing, comprising a minimum of 300 hr or more, with breadth and variety in both their treatment targets and methods of engendering change. Approaches to treatment from other domains have been integrated into the treatment of these violent offenders, including motivational interviewing, dialectical behavior therapy, and transdiagnostic integrated approaches to the treatment of personality disorder. Although not many of these newer programs have yet been fully evaluated, they offer the promise of further improving outcomes in an offender cohort that continues to push the boundaries of who and what can be treated successfully.

Violent Offenders: Treatment Outcome Research

Most treatments for violent offenders are intended to reduce the frequency and severity of violent behavior, but this can be a difficult outcome to measure directly, unless the treated person can be

monitored closely (e.g., in an institution). More often recidivism is used as a proxy for criminal behavior; in correctional settings, recidivism outcome evaluations are essential to convincing policy makers of an intervention's effectiveness. Furthermore, because those violent offenders who are the highest priority for interventions are usually prolific and diverse in their criminal activity, treatment of violent offenders arguably should also aim to reduce their other criminal behavior, and effects on other forms of recidivism should also be investigated.

Treatments should be guided by theory, and a crucial component of treatment theories concerns the putative mechanisms associated with the occurrence of violent behavior. Changes in the strength of these mechanisms (e.g., drug and alcohol misuse, violence schemas) and/or how they function are desired treatment outcomes. With the exception of family-violent offenders, treatment outcome research for violent offenders is sparse and often poor in quality. This entry examines whether treatment works with regard to violent offenders and explores how effective treatments work.

Does Treatment Work?

Designing Recidivism Outcome Evaluations

The definitive evaluation design for answering this question compares people who took part in the treatment (i.e., treatment group) with people who did not but were otherwise identical in all important respects (i.e., comparison group). But myriad factors that may themselves be related to outcome can affect those who take part in treatment, so it is preferable methodologically to randomly allocate people to treatment or comparison groups. For various ethical and practical reasons, random allocation is almost never used in violent offender treatment outcome research. But even if it is feasible to randomly allocate only half of those needing or wanting treatment to the treatment, still the two groups may be nonequivalent in important ways that require later statistical controls to be employed to manage the impact of the observed differences.

An additional problem is that treatments should have an attrition rate; that is, not everyone should

complete treatment simply because they started it. Participants ethically must be able to change their minds and withdraw from treatment if they wish; even if as a consequence, they are then resentenced or experience some other negative outcome. Furthermore, treatment providers must be able to deny an offender's ongoing access to treatment services if no progress is made or the service provider or other participants are otherwise at risk of harm from the offender. Many group treatment programs lose up to one third of those who start, mainly as a result of voluntary and imposed *dropping out*.

The problem then becomes that those who complete treatment and those who do not also tend to differ when it comes to important characteristics that also predict recidivism outcome. For example, program dropouts are often higher risk, higher need offenders. This phenomenon explains why treatment outcome research should never rely on treatment noncompleters to serve as the comparison group when determining if treatment was effective for those who did finish it; the recidivism for these noncompleters would be expected to be higher, even if both groups actually stopped treatment at the same point. Because of the problem of accounting for the selective effects of attrition on outcome, even after random allocation to treatment, the most rigorous methodological standard compares outcomes for all those who were *allocated* to treatment with all of those who were not, even though a number of those in the treatment group therefore were only exposed to partial treatment.

Finally, random allocation designs require that the evaluation be planned prior to the treatment being carried out. That is, the design is prospective. Most often with violent offenders, no evaluation was planned at the time the treatment commenced. Consequently, the best achievable design for a study asking the question "Does treatment work?" is a retrospective quasi-experimental design, in which a sample of treatment starters is matched to a comparison sample some time after the treatment was provided. In some cases, the comparison sample has also been exposed to some form of intervention. In those studies, the absolute intervention impact is not being evaluated. Rather, two interventions are being compared with each other, which means the

results are only able to be interpreted if the expected effect size of one of the interventions is also known.

Most commonly, the proportion of those rearrested or reconvicted at least once for violent or other offenses over the time since treatment (or since release from custody for custodial treatments) is the outcome variable. The difference in these proportions for the two groups is the intervention's effect size. Other outcomes can also be used. Occasionally, self-report or the reports of others (e.g., partners) are used to determine program reoffending outcomes, rather than official records only of those offenses that received official sanctions.

Survival time to reconviction is another outcome that is sometimes used. The length of follow-up after treatment or in the community often varies within each sample; perhaps it averages

2 years for each sample, but the range is between 60 days for those most recently released and 3.8 years for those who have been followed up the longest. In this case, time to reconviction can be examined alongside the proportion of those reconvicted. A treatment program may be considered successful if it reduces the speed at which people are reconvicted as well as the proportion who remain conviction free at the time the outcome data are extracted (referred to as *censored* in survival designs).

For example, Figure 1 shows a survival curve for violent reconviction, based on a comparison of a sample of treatment completers with a comparison sample. In this case, the average follow-up time was around 2 years (range 363–1055 days), and in that average time, 38% of the treatment sample and 58% of the comparisons were reconvicted for violence. The figure shows that

Figure 1 Reconviction for violence survival functions for treatment and comparison groups

throughout the follow-up interval, a higher proportion of the treatment group avoided reconviction.

Recidivism Outcome Evaluations

At least three quasi-experimental studies have demonstrated that completing between 150 and 300 hr of group cognitive behavioral treatment that targeted at the needs of high-risk violent offenders was associated with a lower likelihood of reconviction than for an untreated comparison group who were otherwise as similar as possible to the treated group. Several of these programs have included a significant proportion of indigenous offenders who have achieved equivalent benefits from the program as offenders of Western European origins. For example, in one New Zealand prison program, although 62% of program completers were convicted for new violent offenses over 3.5 years of follow-up, the corresponding figure for matched untreated prisoners was 72%. This result suggests that for every 100 men who completed the program, 10 who would have gone on to be reconvicted for violence were not. This size of effect compares favorably with a wide range of other socially important and well-supported interventions. Because this study case matched each prisoner who entered treatment with one who did not—based on age, ethnicity, estimated risk of reimprisonment, and date of release—it was possible to avoid a common but erroneous conclusion that treatment has harmed those who drop out. This conclusion is based on the common observation that noncompleters, who often were at greater risk of reconviction before they entered the treatment program, later were reconvicted at a higher rate than the rate for the whole comparison sample. When each man entering treatment is case matched with a similar man, the effect of treatment on those who did not finish it can be compared with the reconviction rate of a case-matched man who did not attend the treatment. Both are likely to have been at greater risk of recidivism without treatment than the men who completed treatment and *their* matched comparisons. So in this same study, 71% of those who did not complete treatment were reconvicted for violence, along with 75% of the comparison men they were linked to. There is no evidence that starting but not completing treatment

somehow increased the risk for those who dropped out. They did not do as well as those who finished, but they were a little more likely to survive without reconviction than those they were matched to who did not even start the treatment.

There is no absolutely fool-proof way to be sure that the treatment group is identical to the sample of men not treated. There always remains the possibility that the two groups differ not just on treatment attendance but on other variables related to recidivism that was not measured. Further, outcome evaluations are a kind of evidence proof: They show that certain types of treatment *can* be effective. But beyond that, they provide little useful information on *how* to effectively treat violent offenders.

How Does Treatment Work?

How can it be determined whether treatment worked for a particular individual? The answer to this question is often vital for criminal justice decision-making (e.g., release on parole). Recidivism outcome evaluations do not answer it and also do not help to identify what went wrong if a program is shown not to be effective or if there is a desire to increase the impact of a program. For those designing programs and making decisions about how much progress a particular individual has made during treatment, different types of measurement are needed.

The logic of treatment for violent offenders is that particular changeable characteristics contribute to ongoing violent and criminal behavior or, at least, are precursors to it. These are referred to as *criminogenic needs* or *dynamic risk factors*. If offenders with a number of these characteristics are selected for treatment and the treatment focuses on changing these characteristics through, for example, the use of cognitive and behavioral techniques, then the programs should reduce recidivism later. The characteristics selected for treatment at least should be established empirical correlates of recidivism outcomes. Ideally, they would be validated mechanisms for increasing or decreasing recidivism risk, as specified in etiological theories. Examples of variables that may meet both these criteria are criminal and violence-supportive beliefs, alcohol and drug use, and poor emotional regulation. It follows therefore that if these variables are measured

before and after treatment, or at regular intervals during treatment, and an individual demonstrates positive change on a number of them, that individual will be less likely to be reconvicted later compared to someone who makes little or no change.

Despite the logic that if these intermediate change variables are empirically linked to recidivism, then changing them should change recidivism; there have been very few demonstrations of this change hypothesis. Instead, programs are more likely to have evaluated their effects by simply measuring such constructs as anger and hostility before and after treatment and not attempting to examine long-term links to recidivism. Furthermore, the most common form of measurement is offender's self-report. Offenders are more reliable informants than one might expect, but self-report in any population has limitations, especially when one is rating one's own behavior. The relatively poor psychometric properties of the instruments being used, the limited range of needs measured, and a lack of clarity about how a particular amount of change translates into changes in behavior all likely contribute to limited evidence of treatment effects for violent offenders, based on offender self-report.

One well-designed study used the Violence Risk Scale, a 26-item staff-rated scale, which is based on information from observation, file records, and offender interviews. It measures change by documenting progress on an offender's engagement in behavioral change on each item, over the course of treatment. This study showed that those who made the most change on their treatment needs—criminal attitudes, aggressiveness, association with criminal peers, impulsivity, unstable intimate relationship, and poor community support—were the least likely to be reconvicted for violence. An important methodological feature of this type of study is that higher risk cases have more room for improvement because of their initially higher scores. This study dealt with that problem by controlling for pretreatment scores before examining whether changes were predictive of recidivism outcome.

Final Thoughts

There are few outcome studies for violent offender treatment, which meet even modest methodological standards, with no randomized controlled

trials yet having been published for a general violent offender sample. The current research suggests that violent offender treatment can reduce recidivism and probably does so by reducing the strength of dynamic risk factors. The very small volume of research prevents any stronger conclusions from being reached.

VOCATIONAL EDUCATION

Vocational education is education and training to prepare individuals for work. Most incarcerated offenders will reenter society. Employment and education are considered important protective factors in reentry, as they are often associated with decreased criminal behavior. Therefore, vocational

education is an important component for public safety. This entry provides the history of vocational education for offenders, provides a definition of terms, discusses the vocational needs of offenders, discusses effectiveness and costs of vocational education, and concludes with proposed areas of further development.

History

The idea of educating offenders is not new and, according to the Correctional Education Association, has existed in the United States even as early as the 1700s. However, providing education for inmates has sometimes been a controversial issue. In the late 20th century, rehabilitation programs were reported as ineffective, although such assertions have since been refuted by numerous research studies. The development and progress of education for offenders has been slow, however, with inmates in the late 20th century and early 21st century still leaving prisons with low levels of education obtainment, placing them at risk of reoffending.

In the early 21st century, it appears that at least some governmental leaders are noticing the rising costs of incarceration and recidivism. Thus, rehabilitation programs, such as vocational education, are getting some attention as an important component of effective reentry. Yet more efforts are needed for more quality vocational educational opportunities for offenders. Specifically, there is a need for more vocational education programs for offenders that follow the principles of effectiveness, developed by Don Andrews and James Bonta, such as targeting multiple risk factors and tailoring programs to the individual needs of the offender.

What Is Vocational Education?

The U.S. Department of Education, using the 1990 Perkins Act, defines vocational education as education that prepares individuals for jobs as well as increases their knowledge in a subject matter area, outside of a bachelor's degree. These can include not only academic courses but also skills in solving problems, skills and technical training in specific occupations, and the development of positive attitudes toward work.

Types of Vocational Education

The U.S. Department of Education divides vocational education into two types: secondary and postsecondary. Secondary vocational education is the more common of the two, ranging from career counseling and employment readiness as well as skills for specific occupations. Postsecondary vocational education is less common and consists of advanced education, which prepares individuals for specific careers, through training in institutions such as community college or other technical schools.

Correctional education appears to be a type of vocational education for offenders, often inside prisons. A common type of vocational education for offenders offered in prisons is the General Education Development (GED), with several states strongly encouraging offenders to complete before leaving prison. Many offenders have not graduated from high school, so the GED is critical, as completion of a GED or graduating high school is often required to obtain postsecondary training. Prisons, such as those in several states, offer technical training in areas such as welding, heating and air conditioning, and autobody repair, which train the offenders in specific skills. Furthermore, prisons sometimes grow their own crops, thus training in agriculture can also take place. Sometimes inmates have opportunities to work in the prison as barbers, cooks, or janitors, for example, and might learn different skills in this way. Pay is often minimal for prison jobs.

Vocational Education Needs of Offenders

Many offenders come to prison without any legal employment history, poor social skills, low social and financial capital, and low education obtainment. Offenders will often leave prison with an institutional mentality, little social and financial capital, and few opportunities and support in the community. In prison, where criminal peers surround them, they may have sharpened their attitudes and behaviors consistent with reoffending.

When seeking employment, offenders face many barriers, most strongly bias from employers concerning their criminal record. However, some offenders either have never been employed or have little work experience and are thus unprepared and unqualified for the world of work. Along with

obtaining employment, keeping employment is also important. Years in the prison environment may have taught offenders how to live in an institution with other inmates and less on how to live in a society with nonoffender populations. Specifically, offenders need to learn soft skills such as anger management, social mores, communication skills, and responsible living skills (e.g., money management and showing up to work on time without abusing substances). Other barriers include transportation, discrimination based on appearance or race, and poor attitudes toward work such as unwillingness to work, hostility toward employers and peers, and a lack of positive work ethic. Furthermore, the history of illegal behavior can often draw the released offender back into the network of antisocial peers that might provide illegal work. One way to increase offenders' eligibility for employment is to provide skills that increase their qualifications and employability in the job market. Therefore, relevant vocational education is one way to overcome at least some of these challenges.

Many states and federal prisons have some form of vocational education, particularly GED programs or courses at the high school level. Advanced education, though, is typically not as readily accessible in prisons across the country. This can be limiting, as a growing body of jobs in the 21st century requires advanced knowledge, particularly in technical fields. Furthermore, even in facilities in which vocational education appears available, many inmates who lack educational qualifications are not participating. Among the least available offerings for inmates is career counseling, which may be important in motivating offenders toward education and helping them identify their specific work interests and skills as well as helping them develop supports and attitudes to overcome work barriers.

Another barrier for offender vocational education is public policy that historically has had a punitive approach toward offenders and less of a rehabilitative one. This punitive approach makes the education of criminals a controversial issue at times. Perhaps it is also a reason why the focus has traditionally been on longer sentences and less on rehabilitation. Yet offenders with few skills and training upon release are less likely to find jobs and thus may return to criminal behavior, costing states in regard to tax dollars and public safety.

Effectiveness

Numerous studies indicate the overall effectiveness of vocational education, with several indicating that it is effective in reducing recidivism. There are limitations to these studies, however, as the majority of these studies lack the most rigorous methodology. Specifically, there is a need for more research on vocational education utilizing randomized control group designs. Furthermore, while most published studies on vocational education effectiveness examine recidivism, there has been much less investigation on employment outcomes. Current research also lacks an understanding of the changes within the offender, such as attitudes most associated with career or criminal outcomes. Investigations that study these factors may provide further evidence of the internal factors within the offender, which lead to successful outcomes.

Despite these limitations, it is clear from the published literature that as an aggregate, at least for those who self-select into vocational education programs, there does appear to be a reduction in criminal behavior. This may indicate that those already motivated to join vocational education programs are the most likely to benefit. Such findings suggest that vocational programs could benefit when combined with psychological interventions such as career counseling to encourage offenders to complete the programs. Such career counseling could also help offenders with their work-related interests and skills. Incorporating interdisciplinary research, such as from the field of vocational psychology, could lead to the development of more theory-based education programs that incorporate effective principles of career intervention.

Costs

In 2018, the costs of incarcerating one adult offender can range from approximately US\$30,000 to US\$40,000 per inmate per year, depending on the state in which the offender is incarcerated. When considering the millions of inmates in the United States, the total costs of incarceration are estimated at tens of billions of dollars and are among the most expensive state expenditures. Thus, even the most premium vocational education programs would be considered inexpensive compared to the costs of incarceration. Furthermore, ex-offenders who are gainfully employed

are less likely to be on welfare or some other form of public assistance and would be able to contribute to society through tax dollars. Therefore, if vocational education can be used to reduce the risk of recidivism and increase employment, cost savings provide an additional reason to encourage such programs.

Areas of Further Development

Considering that unemployment and low education are risk factors for a return to criminal behavior, vocational education is one way to overcome this risk. Thus, more opportunities for vocational education for offenders as well as ways to motivate offenders to take part in these opportunities (e.g., through career counseling) are needed.

Quality vocational education that incorporates the principles of effective intervention is an area of further development, particularly utilizing the principles of effective intervention advanced by Andrews and Bonta. These principles suggest that programs need to be responsive to the specific individual differences of offenders. For example, African American offenders are overrepresented in prisons, thus culturally relevant interventions for African American inmates could be valuable. Along these lines, the population of women in prisons is growing; therefore, more vocational programs that are tailored to the interests and needs of women are needed.

In addition, multiple risk factors could be targeted in vocational education, such as poor attitudes toward work or unwillingness to work. This might encourage offenders to obtain and keep jobs upon release. Finally, public policy might include funding for increased prison-based vocational education as well as increased career counseling for offenders so that offenders can reenter society with less difficulty.

VOLUNTARY INTOXICATION

Approximately 60–80% of persons arrested for a crime in the United States test positive for illicit drugs or alcohol shortly after arrest and more than 40% report having been under the influence of drugs or alcohol at the time of their offense. Courts and forensic experts are frequently called upon to consider whether intoxication at the time of an offense might lessen or increase a defendant's criminal culpability and whether the person would be amenable to substance use disorder treatment in lieu of a more punitive sentence. Resolving these matters depends largely on whether the defendant became intoxicated voluntarily, whether the degree of intoxication was foreseeable, and whether the individual has a clinically significant substance use disorder or associated mental health disorder that requires treatment.

Clinical criteria govern the definition of intoxication and the determination of whether a defendant needs treatment, whereas legal criteria govern the elements of voluntariness and foreseeability. Intoxication is defined clinically to include problematic cognitive, emotional, or behavioral

changes that are caused by the recent ingestion of a psychoactive substance and that are usually reversible upon cessation of usage. Common physiological effects include belligerence, mood lability, and disturbances in judgment, impulse control, memory, attention, perception, or psychomotor coordination.

Legal criteria define intoxication as voluntary if it resulted from the intentional or willful ingestion of a substance that is known to have intoxicating properties. Voluntary intoxication is distinguished in law from involuntary intoxication and pathological intoxication. Involuntary intoxication is defined as intoxication that was induced by coercion, duress, or an innocent mistake of fact (i.e., a reasonable belief that the drug was a nonintoxicating lawful substance). Pathological intoxication is defined as intoxication that is grossly excessive in degree given the amount and type of substance that was ingested.

Pathological intoxication requires an additional element of nonforeseeability. The defendant must lack actual knowledge about the potential effects of the substance on his or her behavior and must not have reason to know about such effects. If a defendant had experienced an unusual reaction to a substance in the past, or if the effects of the substance are generally well known, the law will typically view the intoxication as voluntary. Courts are generally reluctant to label intoxication as pathological if it was induced by an unanticipated reaction to illicit drugs or alcohol because these substances are widely known to have intoxicating properties. Pathological intoxication is more likely to be recognized in cases involving an idiosyncratic reaction to prescribed medication. However, courts are likely to view intoxication as voluntary if a defendant mixes prescribed medication with illicit drugs or alcohol because such combinations can foreseeably lead to intoxication.

Diminished Capacity

To be found guilty of most crimes, a defendant must not only commit the criminal act (*actus reus*) but must also have the requisite mental state to have committed that act (*mens rea*). Only a narrow category of mostly nonserious crimes, referred to as *strict liability* crimes, does not require a *mens rea*.

Some crimes are predicated on a *mens rea* of recklessness or gross negligence, such as reckless endangerment or negligent vehicular homicide. To be guilty of such a crime, the defendant must have ignored a substantial likelihood of causing harm, even if the harm was not intended. Courts typically view voluntary intoxication as evidence of gross negligence or recklessness because it is generally foreseeable that intoxication can lead to unintended harms.

The matter is more complicated for crimes requiring intent. There are two types of intentional crimes: general intent crimes and specific intent crimes. General intent refers to any intention to commit an unlawful act regardless of whether the person intended to violate the law. Specific intent requires a further degree of deliberation or premeditation to violate the law. For example, if a person knowingly enters a house without lawful permission, then he or she may be guilty of the general intent crime of trespassing or breaking and entering, even if there was no intention to commit a crime on the premises. If, however, the person entered the house with the deliberate purpose of committing a theft or robbery therein, then he or she may be guilty of the more serious specific intent crime of burglary.

In many states, defendants can argue that intoxication prevented them from forming the requisite intent to commit certain intentional crimes. This defense is referred to as *diminished capacity*. Where a diminished capacity defense is available, it is of little consequence that the defendant voluntarily chose to become intoxicated. The controlling question is whether the defendant had the additional intent to commit a criminal act. In such cases, the effect of intoxication may be to reduce criminal culpability to a lesser included offense. For example, the specific intent crime of burglary might be reduced to the general intent crime of criminal trespassing, or trespassing might be reduced to a crime predicated on recklessness, such as disorderly conduct. Because this defense is viewed by some constituencies, such as victims' rights groups, as being too lenient on crime, a handful of states have passed legislation barring voluntary intoxication from forming the basis of a diminished capacity or other criminal defense.

A national survey conducted in 1999 found that approximately one third of U.S. states and

territories permitted evidence of voluntary intoxication to negate the mens rea element of either general intent or specific intent crimes, approximately 40% only permitted such evidence to negate mens rea for specific intent crimes, and a small percentage (about 6%) limited such evidence to first-degree murder cases. Nearly one quarter of jurisdictions barred such evidence in all criminal defense cases.

Insanity Defense

If all of the elements of a crime have been established, including intent, in relatively rare cases, some defendants may nevertheless be found not guilty by reason of insanity. The crime must have been the product of a serious mental disease or defect, such as a severe psychotic disorder or organic brain syndrome. In addition, there are other tests or *prongs* that must be satisfied for an insanity defense to be successful, and different jurisdictions apply different prongs or combinations of prongs.

In all states, a defendant may be found not guilty by reason of insanity if he or she failed to appreciate the nature or quality of the act. For example, if a defendant strangled his wife believing (e.g., as a result of a drug-induced psychotic delusion) that he was squeezing a lemon, then he did not appreciate the nature or quality of what he was doing. Alternatively, many states will also allow an insanity defense if the defendant failed to appreciate the wrongfulness of the act. For example, if a defendant strangled his wife believing she was really the devil and he was saving the world, then he knew what he was doing but did not realize it was morally or legally wrong. Finally, some states may allow an insanity defense if the defendant had an irresistible impulse to commit the crime or could not conform his or her conduct to the requirements of the law. For example, if a defendant strangled his wife knowing that it was wrong but couldn't resist the voices in his head telling him to do so, then he understood the nature and wrongfulness of his act but could not stop himself.

In virtually all states, voluntary intoxication, by itself, cannot form the basis of an insanity defense. Regardless of which insanity tests a jurisdiction applies, the cognitive or volitional impairment

must be the product of a mental disease or defect. Mere intoxication, without more, does not satisfy the legal definition of a mental disease or defect. However, a substantial minority of jurisdictions will permit an insanity defense if the chronic use of drugs or alcohol resulted in a *settled insanity*. As a result of long-term or serious usage, the defendant must have an independent psychiatric syndrome, such as substance-induced psychosis or dementia, that predates and continues beyond the incident of intoxication that is linked to the crime. The traditional rule required the substance-induced insanity to be permanent; however, some cases have held that a mental defect may be sufficiently *fixed* to satisfy the permanence requirement if it is present for a substantial period of time before and after the instance of intoxication in question, even if it eventually resolves.

Establishing a fixed or settled mental disease or defect is not sufficient. The defendant must also prove that the condition prevented him or her from understanding the nature or wrongfulness of the crime or from conforming his or her conduct to the requirements of the law.

An insanity defense is easier to establish in cases involving involuntary intoxication or pathological intoxication. The law views defendants as less criminally culpable if their intoxication was unforeseeable or unintentional; therefore, such defendants are more likely to avoid a finding of guilt. Again, establishing involuntary or pathological intoxication alone is not sufficient. The defendant must also prove that, as a result of the intoxication, he or she did not understand the nature or wrongfulness of the crime or was unable to conform his or her conduct to the requirements of the law.

Automatism Defense

In rare instances, extreme intoxication or extreme idiosyncratic reactions to a substance may cause symptoms of delirium or dissociation, in which the person is largely unaware of his or her actions or surroundings. Under such circumstances, the individual might be considered, in essence, to be unconscious of his or her actions. In these so-called automatism cases, the law may view the individual as not having engaged in the actus reus (requisite act) of the offense. Similar to the

diminished capacity defense, the automatism defense is unavailable if the defendant knew, or had reason to know, about his or her hypersensitivity to the substance.

As a practical matter, the automatism defense is almost never raised successfully in the United States because of the rare fact patterns that would justify its application. In the absence of a severe dementia, delirium, or dissociative state, it is difficult to imagine a scenario that would support an automatism defense.

Substance-Induced Amnesia

Studies indicate that substance-induced amnesia, commonly referred to as *blackouts*, is reported by between 20% and 80% of criminal defendants. Many defendants are surprised to learn that the presence of a blackout is irrelevant to their criminal culpability. The dispositive question is whether the defendant intended to commit the crime. There is no requirement that the defendant also remembers the crime.

The presence of a confirmed blackout is also largely irrelevant to the question of whether a defendant was capable of forming criminal intent. Studies reveal that substance-induced amnesia reflects focal deficits in the ability to transfer information from short- to long-term memory and has negligible collateral impacts on consciousness, attention, planning, self-awareness, or social skills.

Amnesia may, however, be viewed as one factor for a court to consider in deciding whether a defendant is competent to stand trial. If defense counsel cannot reasonably reconstruct the events surrounding an alleged crime from extrinsic sources such as eyewitnesses or physical evidence, a court might find in rare instances that the defendant is unable to mount a fair defense.

Sentencing Mitigation

Evidence of voluntary intoxication is always admissible in capital sentencing cases to mitigate against the death penalty. Defendants are constitutionally entitled to present any relevant evidence which might support a sentence less than death.

In noncapital cases, some states exclude or limit consideration of voluntary intoxication in sentencing. Many states, however, will allow such

evidence pursuant to sentencing provisions that contain insanity-like language. For example, a defendant may be permitted to argue that intoxication *significantly reduced* his or her ability to appreciate the wrongfulness of the conduct or to conform to the law. This mitigation standard is less stringent than the comparable insanity prong, which requires the defendant to have been *unable* or *substantially unable* to appreciate the wrongfulness of the conduct or to conform to the law. Intoxication evidence may also be admissible pursuant to a sentencing provision that allows for mitigation if the defendant acted under extreme emotional disturbance or pursuant to a *catch-all* provision that allows any evidence that may reduce a defendant's culpability or increase the likelihood of rehabilitation.

Mitigation is most likely to be successful if the court can impose an effective rehabilitative disposition in lieu of incarceration. In light of the high costs, disappointing outcomes, and racial and ethnic disparities engendered by the mandatory sentencing provisions of the War on Drugs, increasing numbers of jurisdictions are developing treatment alternatives to incarceration. In exchange for completing treatment and satisfying other obligations, participants can avoid a criminal record or receive a substantially reduced community disposition instead of jail or prison.

However, many diversion programs are not effective or evidence based, leading to high drop-out and termination rates. Effective programs deliver proven cognitive behavioral interventions that are documented in treatment manuals; monitor participants continually for substance use, treatment compliance, and other behaviors; and apply certain, swift, and gradually escalating sanctions for infractions and rewards for achievements. The best results are achieved when treatment and supervision services are matched to participants' assessed clinical needs and risk of recidivism. Providing too much, too little, or the wrong kind of services can make outcomes worse by wasting resources, interfering with participants' involvement in productive activities like work or school, and exposing low-risk persons to antisocial peers and values.

Research indicates that participants who have a serious substance use disorder and a high likelihood of criminal recidivism achieve significantly

improved outcomes in programs that merge intensive treatment with supervision, such as drug courts. However, not all defendants require these intensive services. Participants who do not have a serious substance use disorder or high likelihood of recidivism perform just as well or better in less intensive and less costly programs, such as pretrial diversion, standard probation, or a simple referral to treatment. Administering standardized risk and need assessment tools is critical for tailoring effective and cost-effective programs for drug- and alcohol-involved offenders and in doing so contribute to public health and public safety.

VOYEURISM

Voyeurism is the act of watching or filming another person, without his or her knowledge, engaging in a private act (e.g., undressing, having sex, toileting) to gain sexual pleasure. It is considered to be a criminal offense in many Western countries. Currently, the prevalence of voyeurism is considered to be underestimated since it is difficult both to detect and to successfully prosecute. Because voyeurism is considered to be a sexual offense, the consequences of conviction may have serious implications for offenders. This entry addresses the legal and psychological (clinical) elements of voyeurism.

Legal

Voyeurism is considered to be a criminal offense in most Western countries. All U.S. states have laws against voyeurism; however, it only became a criminal offense in the United Kingdom in 2004. The penalties range from a fine to imprisonment for up to 3 years. Sentencing judgments are made based on the level of culpability and the degree of harm involved in the offense. Culpability factors include the level of planning, whether the perpetrator exploited a position of trust, and whether

the victim was recorded. Raised harm indications include recordings being made available to others and the victim being observed in his or her own home. As well as fines or imprisonment, sentencing could result in an offender being placed on a sexual offenders' registry or being excluded from taking certain jobs.

Prevalence

The official record of voyeurism incidence is considered to be underestimated because voyeurism can be difficult to detect and convict. A key element of the offense is that it is done for the sake of sexual pleasure, and this can be hard to prove. For example, in cases in which someone has filmed others going to the bathroom in a public place, a sexual motivation for the offense can be difficult to ascertain, unless the suspected offender admits it. In the absence of this, a more appropriate conviction might be a public order offense (e.g., gross indecency). In this situation involving filming in a public bathroom, the degree to which the person was engaging in a *private act* may also be uncertain, given that it occurred in public place. Most Western countries take the view that it is private if the person may have a *reasonable expectation* of privacy. Another reason that voyeurism may be underreported is that people will not always be aware that they are the victims of crime because the offenders generally aim to conceal themselves from the victims in order to watch unnoticed. Unlike many other sexual offenses, voyeurism tends to be perpetrated against strangers, which can also hinder the detection and conviction process as identification is more difficult. Therefore, looking at official records of voyeurism is not a reliable way to measure prevalence.

Other means of measuring prevalence are to ask people in the general population how often they engage in voyeurism and to ask people convicted of other sexual offenses if they have engaged in voyeurism. Using these sources of data, voyeurism is estimated to be a common sexual offense. Different subgroups of the general population have reported varied prevalence rates for voyeurism; for example, a 1991 study of the U.S. male student population recorded voyeurism at 42%, a 2006 study of the Swedish general

population has recorded it at 8%, and a 2016 study of the Canadian population recorded 50.3% for men and 21.2% for women. The lifetime prevalence of voyeurism is considered to be at 12% for men and 4% for women. As a result of the difficulties with measuring, detecting, and convicting voyeurism offenses, very little has been established about the reoffending rate. However, samples of convicted offenders self-report incredibly high incidence rates, with victims numbering into the hundreds, suggesting that it is a highly repetitive behavior for some offenders.

Nature of the Offense

Voyeurism is considered to be a noncontact sexual offense because the perpetrator does not have any physical contact with the victim. Because of this, it is sometimes considered to be a nuisance offense. However, voyeurism is known to co-occur with other sexual offenses, particularly exhibitionism (i.e., exposing genitals to nonconsenting others). The effects on the victims of voyeurism offenses should not be underestimated simply because they are noncontact offenses. Most victims of voyeurism are adult women; many fear that the perpetrator is stalking them and may eventually attempt physical contact.

Psychological

Voyeurism is treated as a clinical disorder in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* and is referred to as *voyeuristic disorder*. It belongs to a group of sexual disorders known as *paraphilias*, which refers to a persistent sexual interest with an atypical focus, either on an activity (e.g., rape), a type of person (e.g., a child), or an object (e.g., rubber), or a combination of these. Voyeuristic disorder is diagnosed where the interest has been present in the last 6 months, and the interest has resulted in significant impairment to the person, or the person has acted on the urges with a nonconsenting person. However, if a person has an atypical interest but is not impaired by this and acts on this interest with a consenting other, a diagnosis is not made. In these cases, the behavior may be considered a paraphilia, rather than a paraphilic disorder, recognizing that atypical sexual interests are

not disordered in themselves. People under the age of 18 years are excluded from diagnosis, in recognition that early sexual experimentation and curiosity may not be pathological but a function of development.

Most people who meet the diagnostic criteria for voyeuristic disorder are males. Very few women are diagnosed with a paraphilic disorder, and while there is uncertainty about exactly why this is, it is probable that societal views about women's sexual behavior reduce the likelihood of reporting and conviction in some cases. Voyeurism has been more commonly observed in the case histories of men who are convicted of raping adult women and less common in those who have offended against children, which suggests that while voyeurism can co-occur or lead to contact sexual offending, it does not have a notable relationship to pedophilia (i.e., a sexual interest in children).

In convicted samples, the behavior is commonly observed as beginning before the age of 15 years and continuing into adulthood, suggesting that in those that do offend, it is a persistent problem. As a result, noncontact sexual offending is considered to be a marker of raised risk of reoffending and features in the sexual offending risk assessment tool, Risk Matrix 2000.

Theories

Compared to other paraphilias, voyeurism has received little research attention, and as such, the understanding of its etiology (i.e., causes) is limited. There are several theories that attempt to explain its development and maintenance, although these need more empirical attention to test their utility. A key theory sees voyeurism as a courtship disorder. This theory proposes that there are four stages to the courtship process: looking for a partner, pretactile interaction, tactile interaction, and sexual intercourse. It suggests that perpetrators of voyeurism are unable to progress through the usual stages of courtship and instead are stuck in the first phase: looking. The premise of this theory is that perpetrators want a relationship but do not have the skills to be able to initiate it appropriately. Research showing that voyeurs characteristically lack intimate relationships, trust in others, and the social skills to approach

partners lends some support to courtship disorder as an explanation of voyeurism. What is not explained by this theory is why voyeurs fail to develop the skills to move through the courtship process; it does not explain those who do not want contact with victims and do not appear to be seeking a relationship.

Another theoretical explanation of voyeurism sees it as a conditioned response, resulting from a pairing, usually accidental, of a sexual response to watching another person. In case studies, voyeurs have reported early salient life experiences (e.g., seeing another person using the bathroom) that hold interest for them and which is subsequently reinforced through ejaculation and masturbation. Because voyeuristic behavior is likely to be secret and thus unlikely to be detected, the strength of the association builds in the absence of punishment. To compound this, voyeurism will not always be rewarding for the perpetrator, resulting in a cycle of intermittent reinforcement, which is known to be one of the most powerful reinforcers. This may account for why voyeurs often describe the behavior as compulsive, or addictive, and why they often engage in hundreds of acts of voyeurism.

The compulsive urges which have been reported by many voyeurs have led some to hypothesize that voyeurism is a form of obsessive-compulsive disorder. Scientific research shows that sexual offending samples have the same deficit in the neurotransmitter serotonin as obsessive-compulsive disorder samples. Serotonin is thought to be responsible for inhibiting moods and arousal and thus urges. This theory has some support from the observation that voyeurs respond positively to drug treatment, which raises serotonin levels.

Treatment

The two key treatment approaches for voyeurism are psychological and pharmacological. Psychological treatments most commonly used are cognitive behavior therapy and behavioral reconditioning techniques. Cognitive behavior therapy aims to help perpetrators recognize and restructure unhelpful beliefs that support the behavior and to recognize and manage deficits in emotional management, coping, and

attachment. There is an emphasis on behavioral change by practicing new skills and behaviors. While there are relatively positive outcomes studies for the use of cognitive behavior therapy with people convicted of sexual offenses generally, these do not report the outcomes for voyeurs specifically, although there is no reason to suspect that their responses would be significantly different from those of other types of sexual offenders. Behavioral reconditioning seeks to reduce sexual arousal to voyeuristic interests and increase arousal to healthy sexual interests. This is usually achieved through masturbatory reconditioning (i.e., the person is encouraged to masturbate only to healthy fantasies) and through some types of aversion therapy (e.g., sniffing ammonia in response to voyeuristic thoughts). Several published case studies related to voyeurs show a positive response to behavior reconditioning.

Pharmacological treatments can act in two ways. One way is to reduce serotonin levels; thus, selective serotonin reuptake inhibitors are administered. These drugs are typically used to treat anxiety and depression but have shown good utility for people with offense-related sexual interests, including voyeurs, who report an increased ability to manage sexual thoughts following medication. The second way is to reduce testosterone and thus sexual drive. Drugs which do this are called antiandrogen, and they are given in tablet or injection form. Due to the action of reducing testosterone to prepubescent levels, these have more severe side effects than selective serotonin

reuptake inhibitors, but those taking them commonly report benefit in reduced sexual urges.

W

WAR CRIMES

War crimes are violations of the laws of war (or international humanitarian law) committed by military personnel (individually or collectively), which incur criminal responsibility. Only when considered in the complex realities of war and the modern world does the definition become problematic. What are the accepted laws of war and do they vary by conflict, by nation-states, and by participants? What are military personnel? In today's environment of international terrorism are nonstate actors such as al-Queda (Khorosan Group) and the Islamic State of Iraq and the Levant (ISIS) military or quasi-military actors and are their acts war crimes? As nation-states vary, so do criminal codes of law. Not all war crimes are comparable or of equal severity. By definition, and by conventions and protocols, war crimes are divided into *grave breaches* and *nongrave breaches*. Nor have war crimes remained constant throughout history (with a few exceptions, such as murder). Not all states sign conventions and protocols recognizing war crimes, and even if they do, not all abide by them.

Development, Conventions, and Protocols

Virtually, since the beginning of recorded warfare, states and armies have been cognizant of the issue of crimes committed during warfare. Nations and militaries have recognized that as brutal as it may be, war needs strictures and structure regarding its

conduct. In one of the earliest treatises on warfare, Sun Tzu warned against harming prisoners of war (POWs), not killing or mistreating civilians and killing only in furtherance of military objectives. The Hindu Code of Manu (Laws of Manu or *Manava Dharma Shastra*; ca. 200 BCE) discussed the illegality of war crimes. The Greeks and Romans mandated regulations for war and provided punishments for violators. For example, truces and cease-fires were part of warfare (for clearing battlefields of wounded and dead), some weapons were prohibited, and treatment of civilians was addressed. Sir William Wallace of Scotland was tried and beheaded in 1305 for war crimes (against English civilians) by King Edward I of England. In the 13th–14th century, the Medieval Code of Chivalry prohibited pillaging and murder and placed restrictions on the weapons of war. Charles VII of Orleans enacted a law in 1439 that held officers responsible for the abuses and ills of their men, and if the officer did not punish the offender, that officer would be punished as the offender. As early as 1625, a full treatment of war crimes was given by Hugo Grotius in his *On the Law of War and Peace* in which he established three rules to govern the conduct of war. Grotius argued that states should establish rules for war that all should obey and that violations should be punished.

In 1863, the Union Army published the Lieber Code (after Francis Lieber, a law professor and survivor of the Napoleonic Wars) as *Instructions for the Government of Armies of the United States in the Field* (General Order #100, Adjunct

General's Office, reprinted 1898), which contained regulations for military behavior; respect for human life; treatment of civilians and POWs; treatment of deserters, hostages, and spies; and murder, among other acts that could be construed as crimes. This manual was also used by European nations for the conduct of war. In the United States, in 1865, Heinrich Hartmann Wirz, Confederate commander of Camp Sumter (Andersonville), was tried and executed for conspiracy and murder over his mistreatment of Union POWs in the camp.

The Hague Conventions of 1899 and 1907 were the first international treaties that codified crimes of war and were heavily influenced by the Lieber Code. The conventions outlined rules for the conduct of international warfare and identified an extensive list of war crimes, including protection of hospital ships, outlawing the use of poisons and balloon bombing, prohibition against expanding bullets, treatment of POWs (land and sea), and the treatment of civilians, among others.

The Geneva Conventions are a series of four conventions and three protocols (1977, 1977, and 2005), all dealing with the conduct of war and war crimes. The First Convention was ratified in 1864 and focused on medical facilities and civilians aiding wounded soldiers. The Red Cross was also recognized as a neutral organization. In 1882, the Second Convention was enacted and applied the First Convention to those wounded at sea and shipwrecked sailors. The Third Convention of 1929 addressed POWs, their protection, and treatment. The Fourth Convention reaffirmed the first three conventions and provided civilian protection during wartime. It also provided rules for treating those sick and injured in the field and at sea. In 1980 and 1981, the United Nations (UN) convened additional conferences in Geneva to add protocols for limiting or outlawing certain weapons, explosive devices (such as land mines), and incendiaries.

In 1925, the Geneva Gas Protocol was adopted, preventing the use of poison gas and biological weapons in warfare.

The UN has taken the lead on war crime issues, attempting to codify war. It passed the Genocide Convention in 1948, nuclear weapon ban in 1961, human rights resolutions and protection of

civilians in a war zone in 1968, and in 1977, under guidance from the Red Cross, Geneva Convention (1949) protocols for national liberation revolutions, protection of civilians and additional treatment standards for POWs. In 1997, the UN led the way for the passage of the Landmine Treaty (Oslo Treaty) that banned landmine and antipersonnel mines.

In 1977, the Geneva Convention was revised and expanded (Protocols I and II) to include crimes committed during *internal wars*. According to the convention, these are crimes committed by a military under sponsorship of their state against citizens or dissident military factions of the same state. Essentially, governments and militaries who wage war against their own population can be tried under war crime statutes. Acts committed during political conflicts such as those in Argentina and Chile, guerrilla wars like that in Nicaragua, and the civil wars in Lebanon, Rwanda, and Sudan would be subject to war crime conventions. The provisions of Protocol II were upheld by the International Criminal Tribunal for Yugoslavia. The International Criminal Tribunal for Yugoslavia also ruled that technical requirements for international war do not need to be present. In 2005, Protocol III was passed protecting the Red Crystal as a Red Cross symbol and prohibiting its use by any state.

Greatly expanding war crime coverage, in 1998, the UN Diplomatic Conference, meeting in Rome, passed a charter establishing the International Criminal Court (ICC) as a judicial body that could try war crimes and other violations of international law. Not only did the Rome Charter establish the ICC, it also defined the court's jurisdiction and crimes it could try. Under this statute, the ICC can try war crimes, crimes of aggression, genocide, and crimes against humanity. The last, crimes against humanity, expands the concept of war crimes to include criminal acts similar in nature to war crimes but committed during times other than during war. For example, the killing of Jews and Gypsies by the Nazis prior to 1939 would be considered crimes against humanity and could be tried by the ICC. Acts of genocide such as those in Bosnia and Rwanda in the 1990s are likewise subject to ICC jurisdiction. Acts of mass disappearance of civilians by a government (i.e., Chile and Nicaragua), even though

not genocide, are also covered. Under the Rome Charter (and the later Genocide Convention passed by the UN General Assembly), war crimes can also be tried as crimes against humanity, if the crime is committed by a military against a civilian population of another country and if the crime is committed during a time of war.

Grave Breaches

In addition to the separation of grave and non-grave breaches being based upon the severity of war crimes, the two categories are separated by the responsibility of states to arrest, extradite, and prosecute war criminals. For grave breaches, states have the responsibility to arrest and prosecute or turn over accused to other states or international tribunals. For nongrave breaches, only the violating state is responsible for arresting and prosecuting. While nongrave breaches may not technically be war crimes, they are still violations of civil law.

The 1945 Charter of the International Military Tribunal at Nuremberg and the Geneva Conventions have defined grave breaches. From the various conventions defining war crimes, the grave breaches include (a) apartheid; (b) certain medical experimentation; (c) deportation of civilians or in occupied territory for slave labor (including servitude in a military); (d) depriving a POW or protected civilian a fair and regular trial; (e) enlisting and/or conscripting children under the age of 15 into a military or using them in hostilities; (f) ill treatment of POWs for persons on the seas; (g) ill treatment of combatants or civilians in general; (h) intentionally directing attacks against the civilian population not in support of military objectives; (i) intentionally directing attacks against buildings dedicated to art, charitable purposes, education, historical monuments, or hospitals; (j) murder; (k) mutilation, cruel treatment, and torture; (l) pillaging and plundering of public or private property; (m) sexual violence of any type, including rape, forced pregnancy, and sexual slavery; (n) taking hostages (including killing hostages) and to include unlawful confinement of protected civilians; (o) torture or inhumane treatment; (p) wanton destruction of cities, towns, or villages or other devastation of same not justified by military necessity; (q) unjustified delays in

the return of POWs; and (r) using the emblems and symbols of the Red Cross or Red Crescent to deceive or in the conduct of war.

For an act to be charged as a grave breach, certain elements of culpability must be established. The act must have been committed primarily by military personnel; it must be an act of violence against civilians, POWs, or enemy soldiers in the field or at sea; it must be an act that involves weapons or methods of unusual cruelty or destruction; it must not be a military necessity; and it must be a violation of the laws and customs of war. Military commanders can be held liable for the actions of those serving under them.

Terrorism and War Crimes

The 21st century has brought unique challenges to the concept of war crimes and crimes against humanity. While most states may adhere, in varying degrees, to the protocols, conventions, and practices of warfare, the first two decades of the 21st century have demonstrated that some developing countries and international terrorist groups have no such constraints and propriety. Groups such as al Qaeda, Boko Haram, and ISIS have routinely and with impunity targeted civilian populations. They have kidnapped and taken young children and teenagers as hostages. ISIS, in particular, has posted online videos showing young children beheading and killing hostages, brutal execution of hostages (and mass executions), beheadings, drowning in cages, and other depictions of brutality, with the executioners hiding their faces behind balaclavas. They openly recruit young teenagers, especially females, over the Internet. Those females who are lured by ISIS are often sexually abused and murdered.

Boko Haram attacks schools and takes young female hostages, secreting them in the jungles of Nigeria and Somalia. In February 2016, Boko Haram terrorists attacked the small farming villages of Kachifa and Yakshari, Damboa, Nigeria, slaughtering villagers by slitting their throats and then stealing the villager's food supplies. They have bombed schools and religious structures, assassinated civilians, and kidnapped women and children. They deliberately target defenseless civilian populations and act in open defiance of protocols and conventions outlining war crimes.

When members of such groups are caught and charged, questions arise about whether they can be tried for war crimes and crimes against humanity and who can do it. The United States has tried terrorists both under war crime statutes (Military Commission Act of 2006) and in civilian courts. In 2008, the U.S. Supreme Court, in *Boumediene v. Bush* ruled that terrorists at Guantanamo Bay are under the protection of the U.S. Constitution and have the right of habeas corpus. Without war crime provisions, terrorists caught and charged under the applicable conventions and protocols may escape justice.

WEAPONS TRAFFICKING

Illegal weapons trafficking accounts for only a small percentage of the billion plus dollar annual worldwide arms trade, but it plays a significant role in crime, terrorism, insurgency, drug trafficking, and other illegal activities. Transnational criminal organizations deal almost exclusively in illegal weapons. Individuals and organizations have used the illegal weapons trade to harm and intimidate unarmed civilian populations and to

expand their criminal enterprises. Illegal weapons trafficking has had a significant impact on the spread of international drug trafficking organizations (DTOs) and has even had an impact in the human trafficking industry. Many of those directly affected by the resulting violence of the illegal arms trade are innocent civilians. The majority of the illegal arms trade involves weapons considered to be *small arms* and *light weapons*. This entry provides an overview of illegal weapons, the individuals and organizations that buy them, and the response by governments to the illegal weapons trade.

Defining Illegal Weapons

In 1997, in the most comprehensive report to date, and a report that is still used as the benchmark by law enforcement, military, governments, and other civilian agencies, the United Nations issued a comprehensive report that classified weapons commonly involved in illegal trafficking. The 1997 report *General and Complete Disarmament: Small Arms. Report of the Panel of Governmental Experts on Small Arms* defined *illegal arms* as small arms and light weapons used by “all armed forces and internal security forces as weapons for self-protection or self-defense, close or short-range combat, direct or indirect fire, and against tanks or aircraft at relatively short distances.” *Small arms* were defined as those used by one person for personal use and light weapons as those used by several persons serving as a crew. Small arms include (1) revolvers and self-loading pistols, (2) rifles and carbines, (3) submachine guns, (4) assault rifles, and (5) light machine guns. *Light weapons* include (1) heavy machine guns, (2) handheld underbarrel and mounted grenade launchers, (3) portable antiaircraft guns, (4) portable anti-tank guns/recoilless rifles, (5) portable launchers of anti-tank missile and rocket systems, (6) portable launchers of antiaircraft missile systems, and (7) mortars of 100 mm or less. Light weapons 3, 4, and 5 can be either handheld or mounted. The United Nations also included ammunition and explosives as part of the illegal arms trade as well as (1) cartridge rounds for small arms, (2) shells and missiles for light weapons, (3) loaded mobile containers for antiaircraft and anti-tank systems (single action), (4) hand

grenades (antipersonnel or anti-tank), (5) landmines, and (6) explosives.

Small arms and small light weapons can all be carried and used by one or two people. Light weapons can be carried by persons, pack animals, and/or light vehicles such as pickup trucks. All are highly mobile (i.e., they can be easily packed and moved, even while in use) and can be adapted for use in a variety of climates, terrains, and conditions. An operator can assemble a light weapon, fire it, and move it to a new position before being identified and targeted by a military or law enforcement source. Light weapons can cause mass casualties in short order or can be used in sustained operations against military armament such as tanks and aircraft. They can also be used against civilian vehicles and civilian aircraft. In November 2002, al-Qaeda-supported terrorists attempted to use light weapons (i.e., antiaircraft weapons) against an El Al airliner carrying Israeli tourists evacuating Mombasa, Kenya, following a hotel bombing which killed 15. Luckily, one missile failed to achieve lock and the operator forgot to disengage the safety mechanism on the other.

These weapons are less complex and require less training for the operators. Most, in fact, can be operated with no training whatsoever. Small arms and light weapons are easy to conceal, which means operators can transport them with little risk of attracting the attention of the authorities.

One of the most significant advantages to the criminal, insurgent, or terrorist is that small arms and light weapons are durable, almost maintenance free, and easily repaired. For example, there used to be a saying that to fix a *knock-off* AK-47 (i.e., one produced in Asia from stamped metal), all one needed was a soft drink can and set of tin snips. Since they are durable, these weapons can operate for an extended period without logistical support.

The Buyers

Globally, the illegal weapons trade involves governments supplying weapons to insurgents, terrorists, cartels, and groups involved in civil wars. Governments can use sympathetic criminal groups to advance government interests in a region and destabilize other governments without world condemnation. It is likely that most weapons being

used by insurgents, Islamic State of Iraq and Syria, ISIS, and other terrorists in Syria, Iraq, Yemen, and other countries in the region are part of the world of illegal weapons trafficking. In fact, there is a positive correlation between illicit market prices for illegal weapon sales in Libya and fatalities in Syria. As prices go up, fatalities increase. A similar correlation holds for ammunition prices in the Middle East and civilian casualties.

In some parts of the world, such as Africa, South America, and parts of Asia, animal poachers obtain weapons via illegal trafficking and sales. Animal poachers routinely use small arms in their trade, thwarting legal efforts to control poaching. Not only have thousands of animals fallen prey to poachers, but numerous game wardens and other law enforcement officials have been killed by illegal small arms.

The *ant trade* in Europe is the major supplier of illegal weapons on the continent and British Isles. The ant trade consists of small operators carrying a few weapons at a time to sell to criminals and terrorists. There are thousands of ants, making it virtually impossible for authorities to stop trafficking or the weapons dealing. Many illegal guns on the mainland of Europe cross through the Schengen Zone between the Eastern Bloc countries into Western Europe.

The ant trade also deals in light weapons. For example, in 2013, in Manchester, England, two police officers were killed with a hand grenade thrown by Manchester gangster Dale Cregan. In 2012, Mohammed Merah killed seven people in Toulouse, France, using weapons purchased through the ant trade. Included in Merah's arsenal were an AK-47 and Uzi machine gun. AK-47s have routinely been used in drug and gang killings in Marseille, France, all obtained via the ant trade. In January 2015, the Charlie Hebdo terrorists used automatic weapons brought to France from Slovakia in their terror attacks that left 12 dead in and around Paris.

In the Americas, DTOs (or cartels) are heavily involved in illegal arms trafficking. Most of their illegal light weapons come from Europe and Eastern Europe. Some larger light weapons (e.g., the rocket-propelled grenade launchers) come from the Middle East and Asia. In the United States, small arms are frequently obtained using straw purchasers (i.e., persons paid by the DTOs because

they can pass the U.S. background checks required to purchase a gun). They come into the United States (or live in the United States), purchase a quantity of small arms, and transport them across the border. Between purchases on the international black market and straw purchasers, the DTOs have amassed millions of illegal weapons. Stories of large weapon caches being discovered by authorities are frequently reported. Almost always, these raids discover large quantities of light weapons. For example, in 2010, in one of the largest discoveries ever made, military and law enforcement authorities found a cache near Higuera, Mexico (only 100 miles from the Texas border), which included over 200 semiautomatic and automatic assault rifles, rocket-propelled grenade launchers and grenades, Barrett .50 caliber sniper rifles with armor-piercing rounds, boxes of grenades, thousands of rounds of ammunition, communication equipment, and *up-armored* trucks and SUVs (i.e., vehicles that have been fortified with armor plating and bulletproof glass).

In the United States, illegal weapons proliferate and make their way into the hands of criminals, terrorists, and gangs via a variety of *iron pipelines*, major highways running from the borders and between states into interior cities. In 2013, New York Mayor Michael Bloomberg estimated that over 90% of the weapons used to commit crimes in New York City were illegal weapons purchased in other states and transported for sale to the city. In 2011, over 320 weapons confiscated or found by law enforcement in New York came from Virginia. Weapons from Florida, Georgia, Ohio, the Carolinas, and Pennsylvania have been trafficked in New York. In all of these *supply* states, there is no limit on the purchase of guns, and background checks are minimal. Guns can be purchased from dealers, gun shows, or other criminals. Iron pipelines operate throughout the country, including in Los Angeles, the Pacific Northwest, and Chicago. Chicago allows no handgun sales in the city and has some of the toughest gun control laws in the country, but many of the illegal guns that end up in the hands of criminals and gang members in Chicago come primarily from Illinois, Indiana, Wisconsin, and southern states (e.g., Mississippi). Many of these are bought on behalf of criminals and gangs by straw purchasers.

The Response

The efforts by governments and law enforcement have failed to stop or even slow illegal arms trafficking. For every law passed, for every measure enacted, and for every proactive program started, weapons dealers find ways to circumvent those efforts. Tougher laws do not seem to work. In the United States, for example, laws that require more complete background checks and mandate tougher penalties for illegal gun sales have had little impact on the flow of weapons in the iron pipeline or across borders. Increased intelligence gathering efforts have had minimal impact on intercepting illegal weapons. Harsher penalties for those caught and convicted have seemingly not deterred the traffickers. Further, some have argued that the penalties are not near tough enough. In the United States, the average prison time for someone caught trafficking weapons is 21 months.

WITHIN TREATMENT OR PROGRAM CHANGE

Treatment and rehabilitation programs for offenders are widely employed in correctional and forensic mental health settings. Usually these interventions aim to reduce criminal risk, improve mental health and institutional adjustment, or some combination of both. Assessing within treatment or program change becomes important for establishing whether the purpose of the referral for treatment has been met. The majority of programs are aimed at reducing recidivism risk, leading to improved community outcomes. Less often, but equally important, are programs or treatments that are aimed at supporting offenders so that they are easier to manage safely (e.g., they are able to be placed in a lower security environment) or, relatedly, increasing their specific responsiveness (i.e., offenders' ability for, or commitment to, undergoing personal change, and to engaging with the services that are available to help reduce their criminal propensity). For example, someone currently experiencing paranoid delusions may struggle to develop a bond to therapists that would allow full participation. Treatment may be focused on remediating these issues, to enable access to other interventions for which the offender is not yet ready. While treatment change is also important for the myriad psychologists working to provide treatment for mental illness in correctional systems, change in programs or treatments that are intended to reduce criminal risk is the most distinctive aspect of the topic in a criminal justice setting. Parole boards and boards that review the legal status of patients held under forensic mental health legislation frequently want information about how much a particular treatment client has changed, what has changed, what effects the changes may have on recidivism risk, and what the implications of change are for the next steps in the management of that person. This

entry focuses on identifying targets of change, methods for measuring change in treatment (i.e., self-report and clinical observation), and the disadvantages of current measurement methods.

Identifying What Should Change

Treatment theories and program logic models that sit under the umbrella of the Risk-Need-Responsivity model posit that to reduce criminal risk—and therefore future recidivism—the targets for change are correlates of recidivism, which are indeed changeable: *dynamic risk factors*. The simplest way to measure risk-relevant change therefore is to measure change on these factors. For example, is there evidence for a reduction in criminal thinking or association with criminal peers in the offender's current living environment?

Another less direct approach is based on how the treatment is theorized to reduce dynamic risk factors. Treatment programs have logic models that describe generically how the program is expected to change those who take part. For example, in one program, the dynamic risk factor for alcohol abuse may be treated through teaching controlled drinking techniques. Therefore, the change measured could be the extent to which the person has learned these techniques and can demonstrate familiarity with them: an examination of specific mastery.

In individual treatment and advanced forms of group treatment programs, the treatment plan is based on an individual case formulation: an idiographic theory of the psychological factors that underpin client's level of criminal risk and how they work together. So, in that situation, a therapist may have theorized that this client's drinking is partly a function of poor emotional regulation: Drinking excessively is a common response to triggers for anger and emotional distress. If so, progress on emotional regulation skills might be the focus of change measurement in treatment.

A third basis for change measurement comes from theorizing about the functions served by criminal behavior. Criminal activity can be understood to be the distal outcome of a sequence of interactions between the person and his or her environment, as it is in offense process models. In this way of thinking, change in risk can be measured by looking for changes in precursors to

offending or in analog behaviors that are theorized to serve the same function as an offense, for that individual (e.g., when instead of assaulting someone, a patient kicks a chair).

Methods of Measurement

Two main methods have been used to measure change: offender self-report and therapist ratings, based on observations of offender behavior. In programs designed to reduce criminal risk, theoretical models (e.g., the Risk-Need-Responsivity model) postulate that change during treatment on risk-related targets leads to a reduction in recidivism. However, few studies have shown in-treatment change to predict recidivism. Reasons for the paucity of support for these links include measurement issues and a lack of stability of change between program completion and recidivism measurement. Finally, institutional environments in particular can make it hard to judge whether changes have occurred because they differ in important ways from postrelease environments.

The best clinical approach to measure treatment change is to use a combination of information sources including offender report, observations of staff or key informants in the offender's life, and the therapist's own observations. In research studies, offender self-report is the most common approach used. A second approach is based on a review of observations, records, or notes made by the treating staff.

Offender Self-Report

Offender self-report is often viewed with a degree of skepticism because of concerns about malingering and lying. The research evidence is somewhat against this view: Studies of the predictive validity of psychometric questionnaires used to predict risk have reported no significant difference in the accuracy of these measures and other forms of risk assessment, assuming that what is measured is itself a correlate of recidivism. Offender self-report scales often show significant amounts of change when scores are compared before and after treatment. Often the pretreatment score itself may be predictive of subsequent recidivism, but the amount of change does not add to predictive accuracy.

According to theory, reductions in dynamic risk factors should lead to lower risk, and therefore, those who make more change should be less likely to be rearrested. But most research does not find a significant relationship between the amount of change and rearrest.

In response to these unexpected findings, some researchers have sought to improve the quality of the research by focusing on psychometric measurement issues. Pretreatment/posttreatment comparisons contain measurement error that varies according to the scale's reliability. Consequently, in determining whether the change made is statistically significant, corrections have been made for the test's reliability. Second, researchers have examined whether the change an offender has made has moved him or her from a problematic or clinically concerning score to a normal-range score on the instrument, based on established norms. This type of shift is referred to as *clinically significant change*. In this approach, changes of this type are considered more valid than changes that leave the client's score in the dysfunctional range or where the client makes progress but was already in the nonoffender range before treatment. Despite these increases in sophistication, for the most part, these advances have not yet yielded evidence linking change to recidivism.

A more pragmatic line of thinking is to question the assumption that a failure to link in-treatment change to a distal outcome like recidivism is really a good test of the theory in the first place. For in-treatment change to be linked to recidivism, progress made in treatment either must lead to a proportionate amount of change during the follow-up or be maintained after treatment (i.e., no relapses). In other words, there should be no notable changes for the person after treatment, which differ from the pattern established in treatment (e.g., people who made no change in treatment should also not change after treatment). Almost no research has examined whether change during treatment is related to change after treatment, whether changes made in treatment are actually maintained, or whether, following treatment, the offender may have been exposed to other forms of support or intervention that also were effective.

Typically, in clinical research, the client attribute that is to be treated (e.g., level of depression)

is measured before and after treatment and sometimes at a third point, say, 6–12 months later. Treatment effectiveness is judged by whether or not there is change and whether that change is maintained. If the patient relapses into depression a year later or commits suicide 2 years later, the response is not to argue that the treatment was therefore ineffective. But this is the logic used to evaluate the validity of treatment change measures in the offender program literature.

Another problem in this research is that often only a handful of dynamic risk factors are measured using psychometric scales, and the analyses often are conducted on each scale independently of the others. It is unlikely that an offender's change on a single dynamic risk factor will be enough to predict recidivism.

Behavioral Observation

Change measurement can be based on observations made by therapists and custodial or care staff over the course of treatment. These types of records can be very systematic, such as when behavioral observation techniques are used to carefully sample and record observations over fixed periods, as is the case in applied behavior analysis research. That is not the method described here. More often in forensic settings, naturally occurring observations are used to update ratings on some form of clinician-rated instrument. Custodial and care staff (e.g., nurses) are in a particularly good position to make such observations as they tend to spend the most time observing patients or offenders. The records analyzed in this method consist of notes made by staff during the course of treatment or observations gathered intermittently by a therapist interviewing other staff as part of a change assessment. Notes on client behavior are most useful when staff are trained in what to look for, records are updated each day, and recording is at least partially structured around behavior that is targeted for change.

Most clinician-rated instruments document change by repeating the scoring of items before and after treatment. A different method is used in the Violence Risk Scale that has 20 dynamic items that are rated before treatment for how strongly present they are. At the same time for all items whose presence has been rated as strong enough

to warrant intervention, a second rating is made on a modified scale based on the extent of engagement in change (i.e., precontemplation, contemplation, preparation, action, maintenance) demonstrated in observations of recent behavior. This change rating is then repeated at the end of treatment, and the difference in the change ratings is then summed across all treatment targets to form an overall change score. Changes on the Violence Risk Scale have been shown to predict recidivism, in support of dynamic risk factor theory.

A third method involves clinical ratings of progress on treatment components. For example, clinicians may rate the extent to which the client at the end of treatment shows an improvement in offense-supportive thinking, shows an understanding of their release plan, or can articulate how better to manage his or her impulsive behavior. However, when these types of ratings are used, they are rarely well-developed psychometrically. Their interrater reliability may not have been established, and the constructs measured may not themselves be predictive of recidivism. Furthermore, there is often no meaningful pre-treatment rating, so it is unclear the extent to which the measured concept may have been contributing to reoffending risk in the first place.

Disadvantages of Custodial Environment Measurement

Most change measurement research has been based in custodial settings. These environments offer greater possibilities for offenders to demonstrate change and have it observed by therapy and custodial staff. But there are two substantial disadvantages to evaluating change in prisons and other restricted residential settings.

First, these residences differ from the environment into which offenders are released in some notable ways. These differences shape the behavior of residents. For example, there may be limited opportunities for a prisoner to demonstrate positive or negative intimate relationship behavior while in prison. Change in child-sex offenders in treatment can be particularly hard to detect in an environment that is typically child-free. These limitations have led to the development of guidelines for evaluating whether behaviors with the

same functions are instead observable. In negative terms, behavior that serves the same function as previous offending can be termed *offense-paralleling* or *offense analog behavior*. For example, it may be possible to discern from how a male offender interacts with female staff whether his behavior toward women remains problematic in a way that suggests that further offending is still likely. On the other side, positive analog behavior, sometimes termed *offense replacement behavior*, may also be observable. An offender who has previously been heavily influenced by criminal peers may be observed spending more time with the most positive members of the residential community or with staff.

The other major problem with evaluating change in a custodial environment is that often the change is being noted during the program. By definition, the environment may therefore be more supportive of change than will be the case later. The challenge then is to evaluate whether the behavior is likely to persist in a less supportive environment.

WITNESS PROTECTION PROGRAMS

Since 1971, the U.S. Witness Security Program (colloquially known as *Witsec* or the *Witness Protection Program*) has relocated individuals whose cooperation with the Department of Justice puts them in mortal danger. Established by the Organized Crime Control Act of 1970 and amended by the Comprehensive Crime Control Act of 1984, the Witness Security Program emerged to protect witnesses and their authorized family members prior to and following testimony. This entry discusses U.S. witness protection programs and their challenges as well as their international influence on popular culture.

Twenty-four-hour protection is provided to witnesses in a high-threat environment (such as pretrial conferences, trial testimony, and other court appearances). Other security measures are extended to mitigate life-threatening situations on an ongoing basis. Cases typically involve racketeering, drug trafficking, murder, and other serious crimes. At present, there are no data indicating whether or not the Witness Security Program has been utilized for terrorism-related crimes; however, it can pertain in such cases.

The program's premise is that the associates of accused or convicted perpetrators are capable of finding any witness anywhere. By providing new identity credentials, however, individuals can be relocated within the United States and hide *in plain sight* without bodyguards. As of 2015, the U.S. Marshals Service continued to report the same figures cited since the early 20th century: Over 8,500 witnesses and 9,900 of their family members had entered the program, with three or four new cases entering the system each week. As of 2018, no more recent data have been released. The Witness Security Program presents a novel sociological model with specific challenges for identity formation and presentation. As such, it has important—though little studied—implications for psychological study.

The Witness Security Program involves two types of witnesses: cooperating defendants in protected custody awaiting trial or serving sentences in prisons-within-prisons (in 2000, the Bureau of Prisons reported 475 protected witnesses within its facilities) and nonincarcerated innocent victim witnesses living among the general population undetected in undisclosed locations. The Federal Bureau of Investigation prepares both kinds of witnesses to testify in criminal trials, provides them with new identity documents, and then hands them off to federal marshals who keep them as safe as possible from retribution. Some participants are relocated only until they give testimony, after which time they resume their former lives and identities. Some retain their original identities until trial and then emerge with new identities after testifying. Others have the new identities concurrent with trial preparation and retain them indefinitely. It is likely that the first category is the most common.

Challenges of the Pretense

Initially, other than providing essential identity documents, the program provided no assistance in preparing witnesses or their participating family members to construct new personae. The program has evolved so that when individuals prepare to enter Witness Protection, the Federal Bureau of Investigation initiates a process they call *acting class*, wherein participants construct and rehearse their basic backstory while living in an interim location. The new birth certificate; social security card; driver's license; and a selection of school records, diplomas, professional degrees, or licenses; military discharge papers; marriage or divorce papers; and credit references that the Federal Bureau of Investigation supplies are scaffolding for this story and the new identity it will sustain.

This differs from identity theft in that the new identity is completely sanctioned and newly generated. This differs from a legal name change, in which the connection between the old and new names is officially linked. Nothing—not bank accounts, credit ratings, addresses, or other means to verify identity—should be connected to the protected witness's new constructed identity. This protocol also differs from a death, which brings one identity to legal closure. Instead, the initial identity simply ceases to generate a trail while the new identity is fabricated so that it presents a credible history that can be built upon indefinitely, as long as the new identity is maintained. The implications for digital identity circulation are not addressed in the published literature, and further particulars are not disclosed by the Department of Justice. It stands to reason, however, that social networking or anything that could link identities through web searching or trawling, such as photographs or biometric registration, would be counterindicated.

The premise of the Witness Security Program is that no person could wholly succeed in suppressing the recognition of the old identity if they were to encounter someone from their original milieu. Upon entering the program, witnesses' former familial, social, and business connections must be severed, but in exchange, their civil liberties are largely intact. In cases where a parent enters the program but their juvenile dependents do not, visits have been arranged by the marshals. These

situations are handled as much as possible like intercity transfers to court; however, there is the potential for the child to be followed and then the parent discovered. It is safest if witnesses commence new lives based on their state-authorized and state-manufactured identities, completely unlinked from their former associates. This is the strongest guarantee that they will be untraceable by anyone who would endanger them. Being accepted by their new neighbors in no way presents a comparable challenge to being unlinked from their old associates. Witness Security puts the onus on the relocated individuals to maintain the pretense in their new locale, but this is almost always manageable. The marshals report that when witnesses obey guidelines, the program never fails. If a chance encounter with an old associate or another protected witness occurs, the marshals will start the identity reassignment and relocation process over again.

Popular culture's fascination with the Witness Protection apparatus, which has no other direct sociological parallels and is a genuine invention of late 20th-century culture, stems from the challenges of how to manage consistent identity presentation. Witness Security Program participants select a standardized lifestyle (e.g., soccer mom, salesman, or business person) and conform to its identity norms. A protected witness in the general population must trust that their identity scaffold, backstory, and ensuing behaviors will suffice to create persuasive performances. No official attempts are made to alter witnesses' recognizability, either physically or vocally. One witness reported that as long as he kept a low profile, it sufficed for him to utilize a hat or sunglasses in order to feel safe. For the vast majority of participants, the scale of maintaining the pretense is manageable. Whether witnesses are innocent bystanders pulled into the vortex of giving testimony or career criminals accustomed to lying, they generally find that they are able to handle the transformation and presentational processes that their new roles entail. Common sense adjustments or substitutions to realign subcultural affiliations, whether ethnic, leisure, or vocational, evolve. This form of cultural relocation resembles the concept of passing in that as something unnoticed the individual subverts reality through a bluff that makes the witness's original cultural locale and matrix imperceptible.

The ongoing pressures of understaffing strain the marshals, and the consequences for protected witnesses can be acute. Marshals' responsibility is for witnesses' safety, not for social or psychological welfare. A protected witness who testified in a 1978 case and then reentered the program a second time in the 1990s commented that nothing else short of incarceration could be so difficult. The sociologist Fred Montanino found that the higher their level of education, the more difficulty participants had in adjusting to the Witness Protection Program. Witnesses who relocate with another adult generally report less distress over an identity change than solitary relocators. Thus, maintaining a spousal or other familial or close personal relationship makes adjustment easier. Nevertheless, some nonwitness participants in the program report that their role is extremely challenging. Not having been involved in criminal activity could exacerbate this because they are unaccustomed to lying or consciously shielding aspects of their lives from others.

International Influence

The U.S. Witness Protection Program has been enormously influential abroad. Comparable programs were established in 24 other countries by 1989. Austria, the Bahamas, Bosnia, Chile, Colombia, Guatemala, Israel, Italy, Kosovo, Mexico, Panama, Russia, Serbia, South Africa, Thailand, and Turkey are among the nations that have subsequently implemented programs on the U.S. model. The scope of witness protection continues to expand. The International Court at The Hague has utilized witness protection measures in prosecutions originating from the former Yugoslavia. In addition to other capital crimes, Canada extends witness protection to survivors of domestic abuse. The United Kingdom operates on a different model. In 1892, the British parliament passed a bill protecting witnesses to Royal Commissions or committees of parliament (though not courts of justice). Britain continues to operate with an informal system of protection for witnesses to capital crimes.

Popular Culture

Prominent protected witnesses featured in news sources and biographies include Nicky Barnes

(a drug dealer) and Frank Salemme, Salvatore Polisi, and Henry Hill (all mobsters). Popular film treatments are numerous. The first was the 1980 *Hide in Plain Sight*, directed by James Caan. For many, Martin Scorsese's 1990 *Goodfellas* endures as the most memorable. Since then, other films and television series have explored the theme in serious and comic modes. These include *Witness Protection* (1999, directed by Richard Pearce), *Witless Protection* (2008, directed by Charles Robert Carner), *Fire With Fire* (2012, directed by David Barrett), *Madea's Witness Protection* (2012, directed by Tyler Perry), and *The Family* (2013, directed by Luc Benson). Television series include Showtime's *Meadowlands* in 2007 (initially released as *Cape Wrath*), USA Network's *In Plain Sight* (from 2008 through 2012), Adult Swim's *Delocated* (from 2009 through 2013), and NRK1 Norway and Netflix's *Lilyhammer* (from 2012 through 2014). *Lilyhammer* focuses on the highly unlikely scenario of a mobster relocated to a small Norwegian city, where his instincts for problem-solving are patently at odds with others in his new community.

WORKPLACE BULLYING

Workplace bullying is a sublethal, nonphysical form of workplace violence experienced by more than one quarter of the U.S. workforce. Perpetrators may verbally abuse, humiliate, threaten, intimidate, or sabotage coworkers on the job. Individuals targeted for the abusive conduct may not recognize what is being done to them, exacerbating the harm they experience. When abusive behavior is recognized, some employers are reluctant to intervene. This entry provides an overview of workplace bullying in the United States, including its characteristics, harmful effects, and causes, then examines why workplace bullying is seldom reported, and finally considers some solution options.

Overview

The Workplace Bullying Institute defines bullying as a repeated health-harming mistreatment of an employee by one or more employees involving abusive conduct that takes the form of verbal abuse, threats, intimidation, humiliation, work interference, or some combination of these. Bullying is not defined by a single emotional outburst by a coworker; rather, bullying involves a chronic pattern and practice of continual or intermittent terrorizing of specifically targeted coworkers (targets).

Psychologist Heinz Leymann first described adult bullying in the workplace as *mobbing*, connoting situations in which there were multiple perpetrators. Although bullying may initially be hatched as a plan by a single instigator, other coworkers may eventually join in and sometimes the institution even lines up against the target. Workplace bullying has also been referred to as psychological violence, emotional abuse at work, workplace aggression, lateral or horizontal violence (primarily a nursing profession term), and abusive conduct.

National scientific studies conducted since 2007 estimate the prevalence of workplace bullying to be between 19% and 37% and include those who are currently or who have ever been bullied. Another one-fifth of workers have witnessed the bullying of others. When extrapolated

to include the entire U.S. workforce, targets and witnesses comprise a group that represents over 65 million people.

According to organizational rank, most bullying is done by a boss who targets a subordinate, but one-third of bullies are coworkers. Some subordinates select targets with more titular power.

Contrasting Characteristics

Some forms of workplace misconduct, such as sexual harassment and racial discrimination, are illegal because the target is a member of a protected status group. However, workplace bullying is considered a *status-blind* form of harassment because its victims are not afforded the same legal protections as victims of status-based harassment.

Moreover, bullying is not merely a workplace *conflict* that can be resolved by conflict resolution techniques (e.g., mediation). It is a zero-sum interaction, not the simple differing on intellectual positions between which middle ground can be found. In general, the two parties, the perpetrator and the target, do not have equal power, and the perpetrator is able to control the fate of his or her target.

Abusive conduct is not a best practice used by competent managers but often the distorted exercise of managerial prerogative. Abusive managers rely on surprises, shock, inconsistencies across staff, and the fostering of internecine battles among staff.

Types of Harm Experienced

Health

Workplace bullying was recognized in Scandinavia in the late 1980s because of its adverse effect on targets' health. Early studies described the trauma resulting from mobbing/bullying. The growing scientific literature documents the extensive range of stress-related diseases traceable to being directly bullied or even from witnessing it. Damage from distress depends on the frequency of weekly incidents and the duration of exposure—typically one to two incidents weekly for at least 6 months, according to

academicians who utilize the Leymann criteria. Cardiovascular (hypertension, ischemia, stroke, cardiac arrest), gastrointestinal (colitis, ulcers), and immunological systems are sensitive to inescapable exposure to bullying. Neuroscience studies reveal that severe stress atrophies regions of the brain responsible for memory, emotional regulation, and decision-making.

Emotional injuries begin with debilitating anxiety and panic attacks. With prolonged exposure, nearly half of bullied targets experience clinical depression for the first time in their lives. For one third of targets, post-traumatic stress disorder is diagnosed. In addition, bullied targets face twice the risk of suicidal ideation as those not bullied, even up to 5 years after the bullying incidents cease.

Social Costs

There are also social costs for individuals who have been targeted by workplace bullies. Targets often are not believed by those responsible for investigating complaints of misconduct or may even be accused of precipitating or inviting the assaults. Even though research indicates that family and friends of the target are sources of support, there is a stigma attached to having been targeted.

Within the work team, targets may face ostracism. Isolation of targets by coworkers, whether physical or psychological, can falsely convince coworkers that they are safe from attacks from the bully. Losing social support of coworkers can compound the targets' distress.

Economic Displacement

Another type of harm wreaked by workplace bullying is economic displacement. Many targets lose their jobs: They may quit, be terminated, or be constructively discharged (i.e., resign due to the hostile environment). Their original income level is lost by 65% of targets. This resulting strain on families can lead to separations, divorces, and vicariously stressed children.

Workplace bullying also harms employers. Tangible costs include, but are not limited to, undesirable turnover (with attendant replacement expenses); absenteeism (by targets and witnesses

suffering emotionally); higher health-care utilization; litigation (defense, settlement, and trial expenses); and lost productivity.

Why Bullying Happens

In the United States, a common explanation for workplace bullying is the perpetrator's personality. The most extreme portrait of a bully is an individual who has *antisocial personality disorder*, characterized as lacking empathy, remorse, or concern for the well-being of others. A less drastic, and more likely, portrait of a perpetrator is a combination of *dark traits* that does not require a personality disorder diagnosis. That is, he or she possesses negative, but subclinical, traits that may include Machiavellianism (i.e., willingness to exploit others to accomplish personal goals); antisocial traits (e.g., meanness, cruelty); narcissism (i.e., an inflated sense of self, superiority); and sadism (i.e., deriving pleasure from inflicting pain on others). There is also evidence that perpetrators bully to compensate for personal, technical, or social deficiencies.

The personality profile of targets has also been studied. Contrary to popular expectations, targets are typically high achievement, ethical, and honest workers whose technical and people skills threaten their perpetrators' self-image. The focus on work that is characteristic of targets precludes their paying attention to organizational politics, the realm dominated by workplace bullies, rendering targets vulnerable.

Targets tend to be people who cannot defend themselves when faced with an unexpected barrage of personalized abusive conduct. Research shows that targets often confront their assailants, but they do so much later than the original incident and generally are not effective in stopping the bullying.

Although common belief is that personality is the major predictor of bullying, studies in which the unit of analysis is organizations suggest that managerial skill and philosophies can explain bullying. Organizations that permit frontline supervisors to be abusive foster a bullying-prone workplace. There need be only a small set of abusers employed and assigned to mid- to high-level positions to affect hundreds, if not thousands, of workers or potential targets. Certainly, bullying occurs when the bullying-prone culture hires

perpetrators and targets who comport with the personality profiles previously described.

Target, Coworker, and Employer Response

Many people wonder why such a widespread, harmful phenomenon is met with so little action by rational actors within organizations. The simplest answer is fear.

Most targets cannot stop workplace bullying, or they would have done so immediately. The target of abuse likely feels personal shame, which is exactly the perpetrator's intention; he or she wants to make the target feel a sense of worthlessness. Shame triggers a dissonance between the knowledge of one's talents and the false message from the abuser. Targets may also experience guilt about not having defended themselves. Coworkers ask why they could not repel the bully.

Research on coworkers' failure to intervene can be traced to studies of the *bystander effect* in the social psychological literature. Even when witnessing a murder, witnesses are often reluctant to intervene. So, it is not surprising that many witnesses to bullying are loathe to intervene on behalf of a colleague. Witnesses may fear becoming the next target. They also may fear saying or doing the wrong thing if they help, so they do not help. They may fear getting involved in an investigation and officially siding against the perhaps more powerful perpetrator. They can also resent the emotional burden associated with compassion and empathy. By socially excluding targets from their circle of allies, coworkers believe that they can have an uninterrupted work life.

In the United States, employer reluctance to address workplace bullying may be explained by the maxim that no policy need exists until mandated by a law. Since bullying is status-blind harassment and no law yet exists, no policy needs to be crafted. Therefore, only early-adopting organizations take the proactive steps of creating policies and holding employees accountable to a nonabuse behavioral standard. According to one Workplace Bullying Institute national study, U.S. employers deny the existence of workplace bullying, discount its impact, rationalize its use as a necessity, and ignore employee requests for relief from such bullying.

Employer reluctance can also be explained from the perspective of a defensive executive. Most

internal complaints are filed and settled at the human resources level. When the bully is a higher level manager or the complaint is filed in a court of law, the executives are notified. When executives perceive their managers as indispensable or valuable to the company, reports of misconduct countering that perception may not be considered credible. As a result, targets seeking relief from abusive managers are considered the bearers of undesirable news about the management team. The complainants are typically branded troublemakers and terminated or constructively discharged. When no behavioral standard exists, manager-bullies are not compelled to change, and bullying is sustained.

Solution Options

Targets

Individuals generally lack the financial resources, organizational credibility, and political network required to stop perpetrators by themselves. This explains the research finding that seven of 10 bullied targets lose their jobs once they have been targeted for bullying, despite there being no rational reason for the onset of bullying. Although employers are becoming aware of the need for psychological safety for workers, research shows that few restore it for workers who are bullied. Nevertheless, individuals who explicitly make their employers aware of the bullying they have endured and the adverse fiscal impact on their employer are better able to adjust to postbullying life.

Unions

Unions are ideal advocates to stop workplace bullying, but unions have two shortcomings. First, the private sector U.S. unionization rate is under 7%, and it is only 11% when government workers are included. So, many workers do not have unions upon which to rely. Second, unions are most effective when their bargained contracts with employers include antiabuse provisions, but employers zealously fight the inclusion of such provisions as threats to managerial prerogative.

Employers

Leaders of organizations have the ability to end workplace bullying. They have the authority to

mandate new codes of acceptable behavior and sanction all unacceptable conduct by means of threatened termination or demotions.

Public Policy

Although employers hold the key to mitigating bullying in the workplace, many are waiting for a legal mandate. The legislatures in over half of the states have introduced an anti-workplace bullying bill (i.e., the Healthy Workplace Bill). The bill holds employers liable for sustaining abusive conduct, subject to civil penalties. If employers were to proactively take steps to prevent and correct abuse, they would be immune from liability. As of February 2018, no state or the federal government has prohibited abusive conduct in U.S. workplaces outside of nondiscrimination laws.

WRONGFUL CONVICTIONS

Wrongful convictions are cases in which a defendant is legally and/or factually innocent, but due to one or more errors made by the legal system, the

defendant is found guilty of the offense in question. When a defendant's conviction is overturned because it is discovered that the state violated the individual's constitutional rights (due to procedural error), this is referred to as *legal innocence*; however, the person may not be factually innocent. Factual innocence means that someone other than the defendant committed the crime (i.e., actual innocence). When a wrongful conviction is overturned or a pardon occurs, the innocent individual is said to have been exonerated. Most of the scholarly inquiry on wrongful convictions focuses on factual innocence. Thus, this entry discusses various aspects of wrongful convictions in the United States, including incidence, consequences, and causes, as well as barriers to and methods for correcting.

Incidence and Demographics

While the actual number of wrongful convictions is not known, it is estimated that between 3% and 5% of convictions may have been made in error. According to the National Registry of Exonerations, of the 2,245 exonerees who have been identified between 1989 and July 2018, 46% were African American; 91% were male; 75% were convicted by juries and 18% pled guilty; 21% were exonerated, in part, by DNA evidence; 39% were falsely convicted of homicide and 14% of sexual assault; and 57% were imprisoned for 5 years (with 9 years being the average number of years spent imprisoned prior to exoneration).

Consequences of Wrongful Convictions

The harms of wrongful convictions include the following:

- As long as the true perpetrator is still in the community, there is a potential risk to public safety.
- Taxpayer money is used to investigate, try, convict, and imprison persons for crimes they did not commit.
- The public may lose trust in a criminal justice system that fails to correct systematic and procedural errors, intentional or otherwise, which contribute to erroneous convictions.
- Many victims report feelings of revictimization, anger, fear, and guilt (especially when they

provided eyewitness identification) upon discovering that a wrongful conviction occurred.

- Innocent defendants' freedom, employment, finances, and relationships can be affected by wrongful imprisonment. In addition, they may experience significant psychiatric and adjustment difficulties as a result of imprisonment.
- It is difficult for innocent individuals, who are still imprisoned, to maintain their innocence while also trying to convince a parole board that they are rehabilitated, have accepted responsibility for their transgressions, and should be released.
- Even if their convictions are overturned, exonerees may have limited housing and employment opportunities, have trouble reconnecting with family and friends, experience social stigma and rejection, and may experience psychological problems.
- Thirty states and the District of Columbia have compensation systems designed to provide assistance (e.g., finances; medical, dental, and mental health care; workforce skills, legal services); however, these systems typically have restrictive approval processes. Of those who do meet the high standards, the actual dollar amount in some jurisdictions (e.g., Louisiana, New Hampshire, Wisconsin) is capped at a low level. In some jurisdictions (e.g., California, Iowa, Mississippi), exonerees who confessed or accepted a plea are ineligible for any compensation.

Causes of Wrongful Convictions

There are several primary factors that contribute to wrongful convictions. The first is eyewitness misidentification, which occurs for a variety of reasons. Witnesses may have been shown a biased live lineup or photo spread, wherein the suspect looks very different from the fillers (i.e., the non-suspects), making it highly unlikely that the eyewitness will pick out the suspect. For example, the suspect may be over 6 ft tall, while the fillers are a few inches shorter; or the photo of the suspect may be in color, whereas those of the fillers are in black and white. In addition, witnesses may feel pressured to pick someone in the identification procedure, due to investigators' suggestive

statements, facial expressions, or body language. Witnesses may also feel guilty if they do not make a selection, which leads to internal pressure to make an identification. Once the identification is made, investigators may inflate witnesses' confidence in their incorrect identifications by making postidentification statements that confirm the identification (e.g., *good job* or *thank you for confirming our suspicion*). Jurors tend to place high importance on this type of evidence when determining guilt or innocence. Of the 2,245 exonerations that have been identified between 1989 and July 2018, eyewitness misidentification was a factor in 29% of wrongful convictions.

A second factor that contributes to wrongful convictions is faulty forensic science. Questions about the accuracy of fingerprint, hair comparison, shoe print, and serology analyses have been raised. In addition, information about these analyses can be incorrectly conveyed during trials. However, juries still tend to believe in the veracity of these analytical methods. In contrast, DNA analysis has been shown to be highly accurate, but only 5–10% of crime scenes contain biological evidence sufficient for DNA analysis. Therefore, police officers have to rely on other, less accurate forms of forensic evidence. Of the 2,245 exonerations that have been identified between 1989 and July 2018, faulty forensic science was a factor in 24% of wrongful convictions.

A third factor that contributes to wrongful convictions is false confessions. These occur when law enforcement officials coerce an innocent person into falsely confessing to a crime. Typically involving psychological coercion and deception, some investigators utilize a set of accusatory and confrontational methods in order to break down suspects' denials. This weakens suspects, causing them to believe the only way to escape the isolative custodial environment is to confess and provide a postconfession narrative. This narrative is shaped and influenced by police behavior (e.g., showing evidence to suspects, correcting errors made by suspects). Some individuals are more susceptible to providing an incorrect, coerced confession, particularly those who are developmentally disabled, cognitively impaired, mentally ill, and young. Of the 2,245 exonerations that have been identified between 1989 and July 2018, false confession was a factor in 12% of wrongful convictions.

Another factor that contributes to wrongful convictions is incentivized informants. These individuals lie for personal gain. For example, they might tell police officers that a factually innocent defendant admitted guilt to them or that they witnessed the crime. Rewards for doing so may include prison sentence reductions or financial compensation. Of the 2,245 exonerations that have been identified between 1989 and July 2018, incentivized informants was a factor in 7% of wrongful convictions.

A fifth factor that contributes to wrongful convictions is inadequate defense representation. It is the charge of the defense attorney to zealously defend his or her client, to protect the defendant from the errors of others involved in the case, and to bring such errors to the attention of the trial judge. However, insufficient defense representation does occur, typically because of scarce funding, lack of motivation, and the absence of quality control. Attorneys may communicate in a rushed or callous manner or may fail to communicate at all with their client. They may fail to prepare sufficiently for trial, not obtain necessary evidence from opposing counsel, carry out superficial investigations, neglect to obtain necessary experts or test forensic evidence, fail to attend hearings, conduct inadequate trial advocacy, or engage in shallow questioning of opposing counsel's witnesses. Of the 2,245 exonerations that have been identified between 1989 and July 2018, inadequate defense representation was a factor in 25% of wrongful convictions.

The final factor that contributes to wrongful convictions is government misconduct. While most prosecutors and law enforcement officials behave ethically, some may not. Incendiary closing arguments, suggestive witness coaching, and intentionally destroying or withholding exculpatory evidence from the defense are examples of prosecutorial misconduct. Police officers may, at times, intentionally fail to provide prosecutors with evidence that may assist in the defense's case and mislead jurors about their observations of the defendant. Both investigators and prosecutors can become susceptible to tunnel vision, whereby their attention becomes focused on evidence that supports a case against a suspect, while ignoring information that endorses an alternative scenario. Of the 2,245 exonerations that have been

identified between 1989 and July 2018, government misconduct was a factor in 52% of wrongful convictions.

Barriers to Correcting Wrongful Convictions

Once found guilty of a crime, individuals typically find it extremely difficult to convince the legal system of their innocence. There are several reasons for this. Judges may need to be persuaded to order a new trial. They are often hesitant to do so because this would mean that they accept the notion that the jury (or judge in a bench trial) was incorrect in its original decision to convict. In addition, some jurisdictions require that defendants file a motion for a new trial, based on exculpatory evidence, within a short time frame following the conviction order. Furthermore, some prosecutor's offices create and maintain an environment that resists postconviction claims because they believe that it creates an image that these offices are soft on crime. The media also plays a role in creating an environment in which the public demands that suspects, particularly those who commit such heinous crimes as rape, murder, and offenses against children, are caught and punished as quickly and as punitively as possible.

Methods to Reduce the Occurrence of Wrongful Confessions

To reduce the likelihood of eyewitness misidentification, criminal justice experts have recommended five guidelines for police lineups. First, the individual who conducts the lineup (i.e., the administrator) should not be involved in the investigation so that he or she cannot influence the outcome of the lineup identification. Second, the witness should be instructed that the administrator does not know who the suspect is in the lineup, if the suspect is present. This instruction should reduce the potential for witnesses to feel guilty if they cannot identify someone and reduce their propensity to rely on the administrator for confirmation. Third, the suspect and the fillers should match the witness's description. If there are features of the suspect that may make him or her stand out among the fillers, an attempt should be made to match the fillers to these. Fourth, to avoid inflation

of the witness's confidence in his or her selection, administrators should not provide any feedback to the witness until after he or she has indicated how confident he or she is in the identification. Fifth, administrators should conduct the procedure in a sequential manner (viewing one lineup member at a time) as opposed to the traditional simultaneous method (viewing all lineup members at once). By doing so, decisions based on relative judgments (picking the lineup member who looks most like the image in the witness's mind) will decrease, whereby decisions based on absolute judgments (picking the lineup member who resembles the image in the witness's mind) will increase.

To reduce the likelihood of false confessions, criminal justice experts suggest that agencies require investigators to record interrogations in their entirety. In addition to focusing a camera on the suspect, it is recommended that one camera should focus on the investigator and another on the entire interrogation room. By utilizing this three-camera strategy, it is anticipated that interrogators will be less likely to engage in potentially coercive tactics to elicit a confession and manipulate a postadmission narrative. Furthermore, juries will be able to review these recordings during trial and ascertain if any coercion, intentional or otherwise, may have occurred. As of July 2018, over 20 states (e.g., North Carolina, Massachusetts, Illinois) required the recording of interrogations and over 1,000 localities voluntarily recorded interrogations.

To limit the occurrence of incentivized informants, experts advise that video recordings of law enforcement conversations with witnesses, as well as witness conversations with suspects, be required. In addition, they advocate for the strict enforcement of discovery rules, including the disclosure of incentives for informant cooperation. Furthermore, they recommend pretrial hearings to assess the reliability and corroborate the content of informant testimony.

To quell the occurrence of government misconduct, creating criminal justice reform commissions (or conviction review units) has been recommended. The goal of these commissions is to investigate cases of wrongful convictions and staunchly advocate for comprehensive reforms in the criminal justice system (including not only government misconduct but also other issues that contribute to wrongful convictions). These

commissions should include members from all aspects of the legal systems with various perspectives and experiences, including victims, concerned members of the public, attorneys, and law enforcement officials. As of July 2018, at least 11 states have established such commissions (e.g., North Carolina, Pennsylvania, California, Connecticut).

While the media, indirectly, can play a role in the creation of a wrongful conviction, it can play a productive role, as well. Publicizing cases of wrongful convictions, including through podcasts and television series, can produce a record of a problem that necessitates attention. This record then can be, and often is, referenced and used in the establishment of effective policy formation and implementation to reduce the occurrence of and identify existing wrongful convictions.

YOUTH LEVEL OF SERVICE/CASE MANAGEMENT INVENTORY 2.0 (YLS/CMI 2.0)

The YLS/CMI 2.0 is a standardized instrument designed to help professionals assess risk and treatment needs in juvenile offenders. The instrument is primarily used to assist in developing intervention and treatment plans in probation and custody settings, but it is also useful in making decisions regarding pretrial diversion and levels of security and supervision in institutional and community settings. The measure has also proved useful in case planning and management with high-risk students in school settings. The instrument is appropriate for use by probation officers, youth workers, court workers, psychologists, and other professionals working in juvenile justice and other social service, mental health, and educational settings. This entry presents the history, format, and scoring of the YLS/CMI 2.0, as well as examines its validity and offers user cautions.

History

The instrument was developed as the youth version of the Level of Service Inventory, an established and widely used risk/need instrument designed for assessing adult offenders. The original version of the instrument was published in 2002, and the revision, YLS/CMI 2.0, was published in 2010. The risk/needs assessment sections

of the two instruments are identical, insuring that earlier psychometric research is relevant to the later version.

YLS/CMI 2.0 is based on the Risk-Need-Responsivity model, a well-researched model designed to guide interventions in judicial and correctional systems. It is relevant to the treatment of those involved in the systems and those at risk of entering those systems. One principle of that model is that interventions with the offender should be guided by standardized and structured assessments of Risk-Need-Responsivity factors and conditions. Risk factors constitute conditions that place the youth at risk of initiating criminal activity or continuing criminal activity (e.g., a history of conduct disorder, drug addiction, criminal associates). Need factors are dynamic risk factors that can be changed and, if changed, reduce the chances of antisocial behaviors. Drug use and criminal associates are examples of risk factors that can be altered and, if so, may reduce risk level. Responsivity factors are characteristics of the youth or his or her circumstances that, while not directly related to criminal activity, represent factors that should be taken into account in case planning and management (e.g., mental illness in a parent, depression in the youth, economic problems in the family). Responsivity factors also include strength or protective factors important in case planning (e.g., a positive and cooperative parent or teacher, high level of maturity in the youth, an interest in sports and other recreational activities).

Format

The YLS/CMI 2.0 is composed of six parts:

Part I: Assessment of Risk and Needs is comprised of 42 items. These items are drawn from the empirical literature on factors associated with youthful criminal activity. Items are divided into eight categories: Prior and Current Offenses/Dispositions, Family Circumstances/Parenting, Education/Employment, Peer Relations, Substance Abuse, Leisure/Recreation, Personality/Behavior, and Attitudes/Orientation. The section is in the form of a checklist where the assessor indicates the presence or absence of the factor. Seven of the eight categories also include an opportunity to indicate strength in the area. The assessor can, for example, indicate the presence of particular strength in the family (e.g., cooperative and helpful father). Similarly, it would be possible to indicate strength under the Attitudes/Orientation section (e.g., strong prosocial attitudes and values).

Part II: Summary of Risk and Needs provides an opportunity to develop a profile of the youth's level of risk/needs within the eight categories and a total risk/need score. Risk/needs ranges are then provided for the total score. Four ranges are identified: low, moderate, high, and very high. Separate ranges are provided for male and female youth and for community and custodial samples. These actuarial scores are based on empirical data.

Part III: Assessment of Other Needs and Special Considerations provides an opportunity to note responsivity and other considerations that might be relevant to case planning. Two groups of factors are included: The first comprises aspects relating to the family (e.g., chronic history of offending in the family, marital conflict between parents, cultural/ethnic issues). The second group includes conditions relating to the youth (e.g., anxiety, depression, health problems, learning disability). Again, the items represent conditions normally not directly related to the criminal activity (although there are circumstances where they may be related), but factors that should be taken into account in case planning.

Part IV: Final Risk/Need Level and Professional Override represents an opportunity for the assessor to override the risk/needs level indicated by the total score in Part IV. The assessor might indicate, for example, that the moderate risk/needs level is too low and raise the estimate to high, or, on the other

hand, the assessor might indicate that the high rating is too high and lower the estimate to moderate or low. The revision should be based on the assessor's perception that factors not represented in Part I may have a bearing on the youth's risk/needs level. The assessor is asked to provide the reasons for the override. This provision is included to ensure that the final decisions about the youth rest with the responsible professional.

Part V: Program/Placement Decision provides the assessor an opportunity to suggest the appropriate level of security or supervision given a particular level of risk/needs. Separate indications are provided for custodial and community services. Categories range from Administrative/Paper to Maximum Supervision provisions.

Part VI: Case Management Plan includes a format that allows the assessor to develop a case plan reflecting the risk/needs factors identified. The format reflects a number of principles of the Risk-Need-Responsivity model. These include the importance of basing case plans on structured assessments, basing decisions about the intensity of service on the level of risk, focusing on specific criminogenic needs of the youth, and considering responsivity factors (including strengths) in the case plan. Other principles guiding the format include an emphasis on the use of evidence-based interventions and the use of multidimensional interventions to recognize the relations among risk and need factors. The format asks the assessor to identify a set of criminogenic needs that should reflect the major need factors identified in Part I (e.g., association with antisocial peers). Then, a specific goal should be identified (e.g., reduce time spent with antisocial peers after school), followed by a specific intervention (e.g., enroll in afterschool athletic program and work with parent to enforce evening curfew) and a time frame indicating the proposed duration of the intervention. A separate section then allows for the development of case plans for the noncriminogenic needs identified in Part III (e.g., addressing the youth's depression and anxiety issues).

Scoring

The YLS/CMI 2.0 is designed for use by probation officers, court workers, youth workers, psychologists, and other professionals working in systems and agencies dealing with juvenile offenders or

those at risk of offending. Assessors should have some experience working with antisocial youth, while some academic background in child development is also desirable. Assessors using the measure should also be exposed to a formal training program in the use of the measure.

Completion of the YLS/CMI 2.0 is fairly straightforward, but the validity of the scores depends very directly on the collection of information on which the assessment is based. The assessment will normally involve an interview with the offender; a structured interview schedule to assist that interview is available. Interviews with parents or other guardians are important, while information from sources such as teachers, principals, and probation officers is also valuable. File information in the form of police reports, prior criminal record, and prior probation reports should be used where available. It must be noted, however, that access to these sources of information may be limited by ethical guidelines.

Construct Reliability

Considerable reliability and validity research has now been conducted with the YLS/CMI 2.0. (Since Part I of the original version and YLS/CMI 2.0 are identical, research with Part I of the original version can be considered relevant to the revision.) Support for reliability comes through satisfactory levels of coefficient alpha and inter-rater agreement. The latter research shows that satisfactory levels of agreement across trained raters can be achieved.

A variety of validity research has been conducted with the measure. Construct validity research has shown significant correlations between risk/need scores from YLS/CMI 2.0 and parallel scores from other established measures, including the Psychopathy Checklist–Youth Version, Child Behavior Checklist, and Disruptive Behavior Disorders Rating Scales. Overall scores from those measures are not parallel with total scores from YLS/CMI 2.0, but subscales are comparable and were used in the evaluations.

Predictive and Dynamic Reliability

Predictive validity is of particular importance, reflecting the extent to which scores from the

measure actually predict future antisocial behavior. Considerable predictive validity research has been conducted with a variety of outcome measures and in a wide variety of settings. This research has generally yielded results supporting the predictive validity of YLS/CMI 2.0.

Outcome variables used in the predictive validity research include police contacts, arrests, and convictions. This research has focused on both general and violent offending. Other outcome measures include institutional infractions, compliance with probation conditions, and postinstitutional adjustment. Validity has been established for boys and girls, various minority groups, and a wide range of national settings, including the United States, Canada, Australia, Ireland, Singapore, Croatia, Spain, and Scotland.

Dynamic validity has been supported in a number of studies. This research demonstrates that increases in the YLS/CMI 2.0 score over time are associated with increased levels of reoffending, while decreases in those scores are associated with decreased levels of reoffending. This demonstrates that YLS/CMI 2.0 is truly a dynamic instrument.

Because of its demonstrated validity, YLS/CMI 2.0 has been adopted in a wide variety of agencies and across a wide range of countries. It has generally been well accepted in those settings and regarded by professionals as a useful tool in their case planning and management activities.

Cautions

Several cautions should be observed when using an instrument such as the YLS/CMI 2.0. First, the instrument should only be used by professionals with training in scoring, interpreting, and applying the measure. Second, the instrument should not be used in a rigid way. For example, an overall score from the measure should not be used as the sole basis for a decision about placement on probation or custody. The scores are designed to aid the professional in making a decision, not to dictate a decision. This is one reason for including the professional override section. Third, care should be used to ensure that the measure does not result in unjustified net

widening. This would occur where a more serious disposition would be provided because a high number of needs are identified in the assessment without regard to other considerations (e.g., severity of the offense). This highlights the importance of developing policies regarding the role of the risk/needs assessment in the judicial process.

Appendix

Resource Guide

All contributors provided a list of additional resources to aid readers wishing to delve even deeper into a topic. These resources include articles and reports, books and book chapters, and websites and other Internet-based documents. For reader convenience seminal works are organized to correspond with the Reader's Guide and by type of resource (e.g., journal articles, books and book chapters, and Internet-based resources). Consistent with the Reader's Guide, resources are categorized into one of the following 13 categories: Biases in Crime Policy and Prevention; Crime Policies; Criminal Justice Legal Processes; International Perspectives; Offender Assessment; Offender-Crime Theories and Typologies; Preparing for a Criminal Justice Career; Prisons and Prisoners; Prison Services and Treatment; Rehabilitation and Reentry; Research in Criminal Psychology; State, Federal, and Private Criminal Justice Agencies; Theories of Crime. It is intended that this resource guide will provide you, the reader, with easily accessible and essential resources in an easy to follow organizational scheme to help you pursue even more information on a topic of your interest.

Biases in Crime Policy and Prevention
